**Table S1.** Computational cost associated with PBE, PBE+ $U=3.9$ ,<sup>1</sup> SCAN, and SCAN+ $U=2.7$ <sup>2</sup> self-consistent-field calculations for four “high quality” experimental crystal structures of BaMnO<sub>3</sub>. ICSD is the Inorganic Crystal Structure Database Collection Code and  $t$  is time. Input parameters are the same as those in the main text.

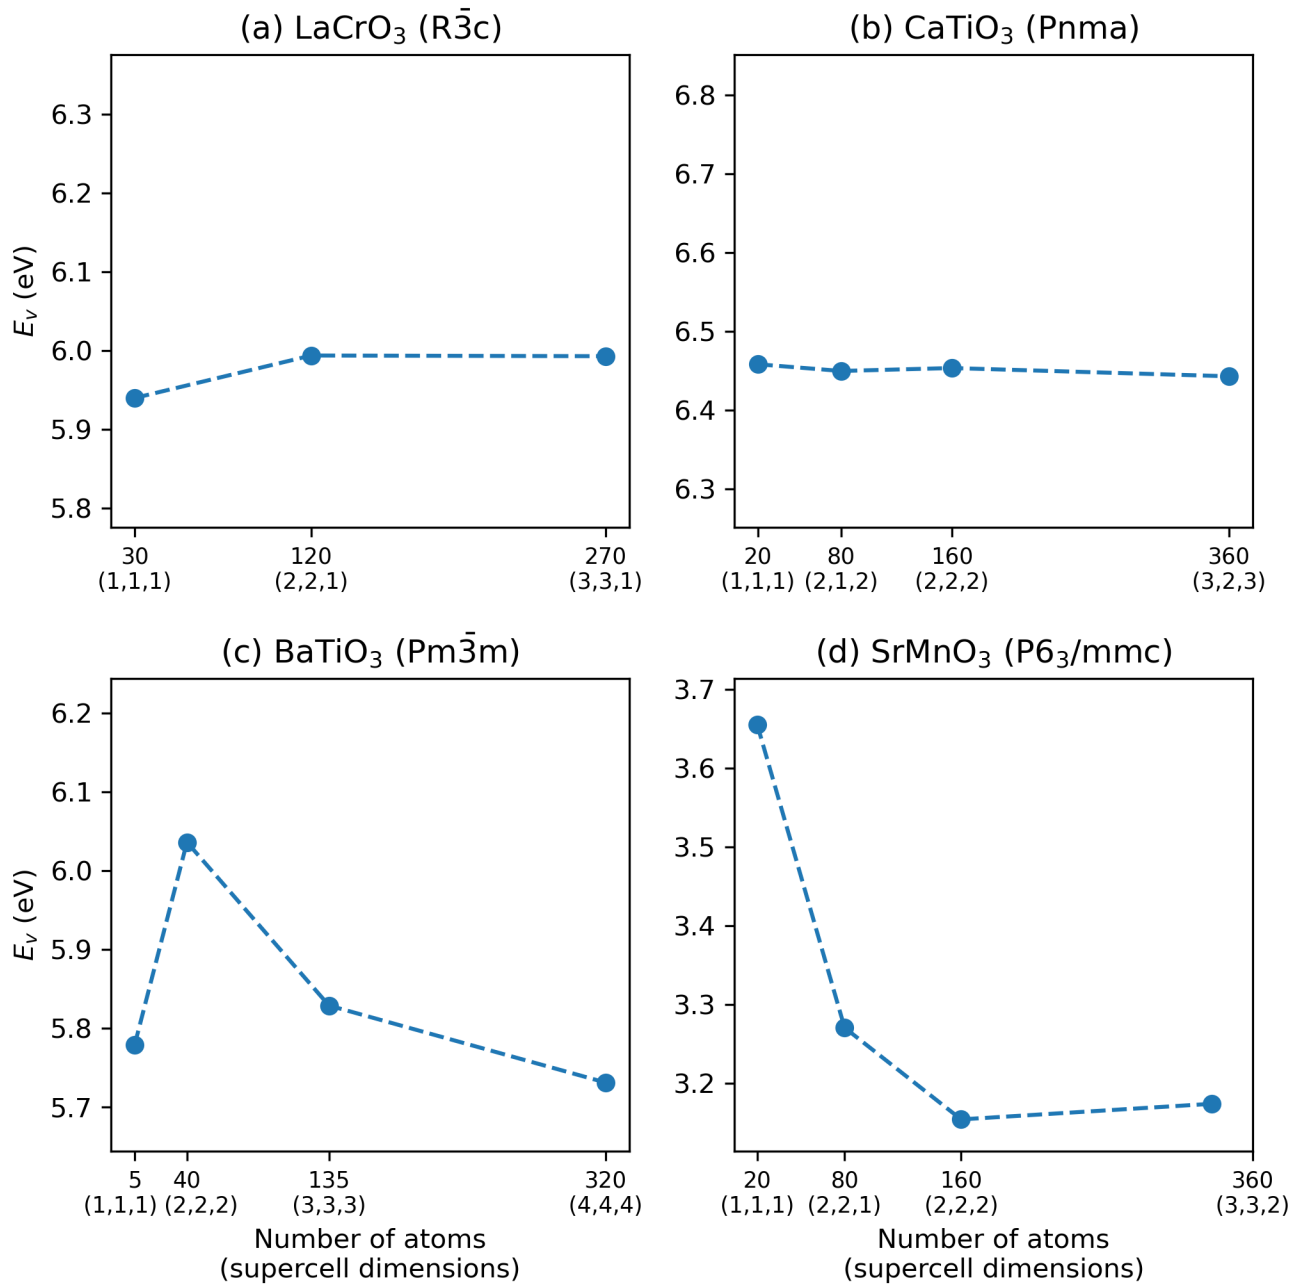

ICSD	Space Group	# Atoms	XC	$U$	$t$ (s)	# Steps	$t_s=t/\text{step}$	min( $t$ )	$t/\text{min}(t)$	min( $t_s$ )	$t_s/\text{min}(t_s)$

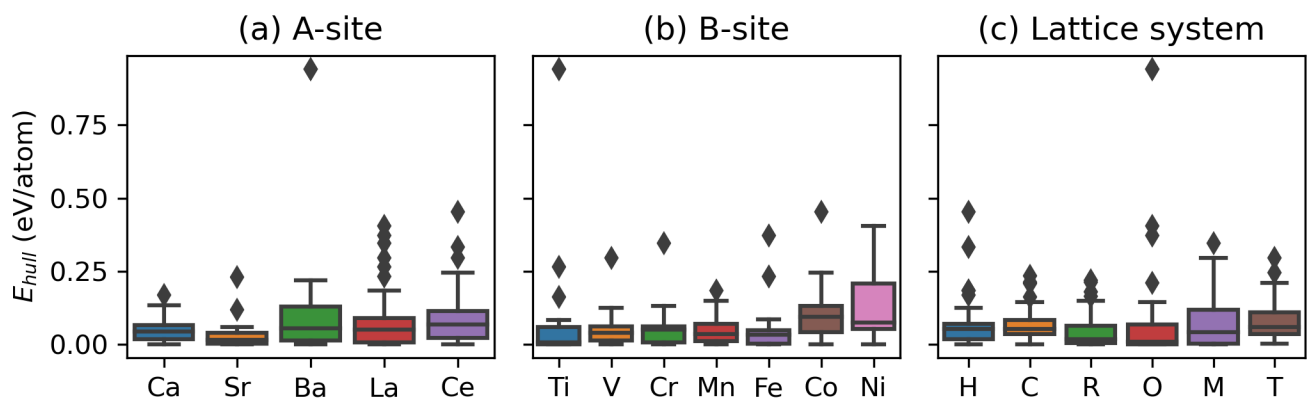

**Figure S1.** Distribution of  $ABO_3$  perovskite structures in the bulk by (a) A-site, (b) B-site, and (c) lattice system. We tabulated structures, total free energies, energies for  $\sigma \rightarrow 0$  where  $\sigma$  is the width of the Gaussian smearing, magnetizations, local charges and magnetic moments, and band gaps for pristine primitive cells and supercells in bulk.csv.

**Figure S2.** Distribution of neutral oxygen vacancy formation energies ( $E_v$ ) for  $ABO_3$  perovskite structures by (a) A-site and (b) B-site. The boxes show the quartiles of the data subsets while the whiskers show the rest of the distribution, except for points that are outside  $1.5 \times \text{IQR}$  (diamonds) where IQR is the interquartile range. We tabulated structures, total free energies, energies for  $\sigma \rightarrow 0$ , magnetizations, local charges and magnetic moments, band gaps, and  $E_v$  for defective supercells in defects.csv.

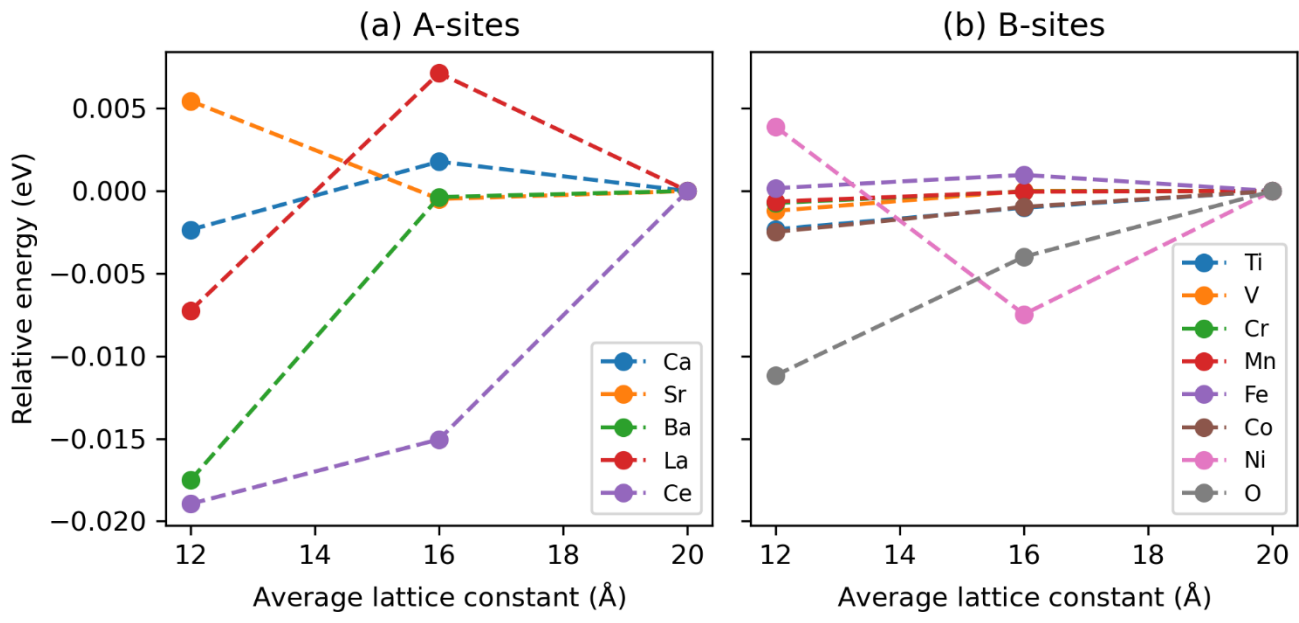

**Figure S3.** Convergence of  $E_v$  in (a) LaCrO<sub>3</sub> ( $R\bar{3}c$ ), (b) CaTiO<sub>3</sub> ( $Pnma$ ), (c) BaTiO<sub>3</sub> ( $Pm\bar{3}m$ ), and (d) SrMnO<sub>3</sub> ( $P6_3/mmc$ ). We did not explicitly perform convergence tests for tetragonal ( $P4mm$ ) and monoclinic ( $P2_1/b$ ) structures since they share similar lattice parameters with cubic ( $Pm\bar{3}m$ ) and orthorhombic ( $Pnma$ ) structures, respectively.

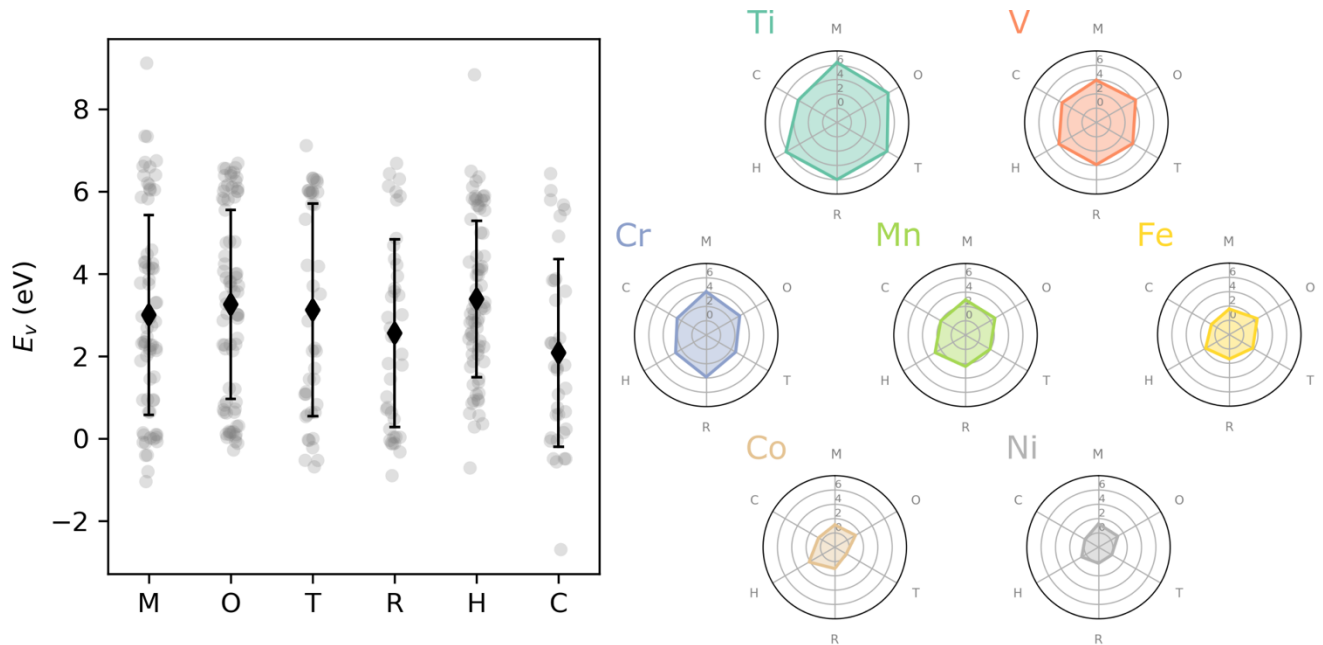

**Figure S4.** Distribution of energies above the convex hull ( $E_{hull}$ ) for  $ABO_3$  perovskite structures by (a) A-site, (b) B-site, and (c) lattice system. The boxes show the quartiles of the data subsets while the whiskers show the rest of the distribution, except for points that are outside  $1.5 \times IQR$  (diamonds) where  $IQR$  is the interquartile range.

**Figure S5.** Periodic trends in experimental cohesive energies in eV/atom,<sup>3</sup> listed below each element. We tabulated cohesive energies in element\_cohesive\_energies.csv. “nan” indicates unavailability of experimental cohesive energies (grey squares).

**Figure S6.** Cell-size convergence of total energies for neutral (a) A- and (b) B-site atoms in their electronic ground states. We tabulated atomic total energies in atoms.csv.

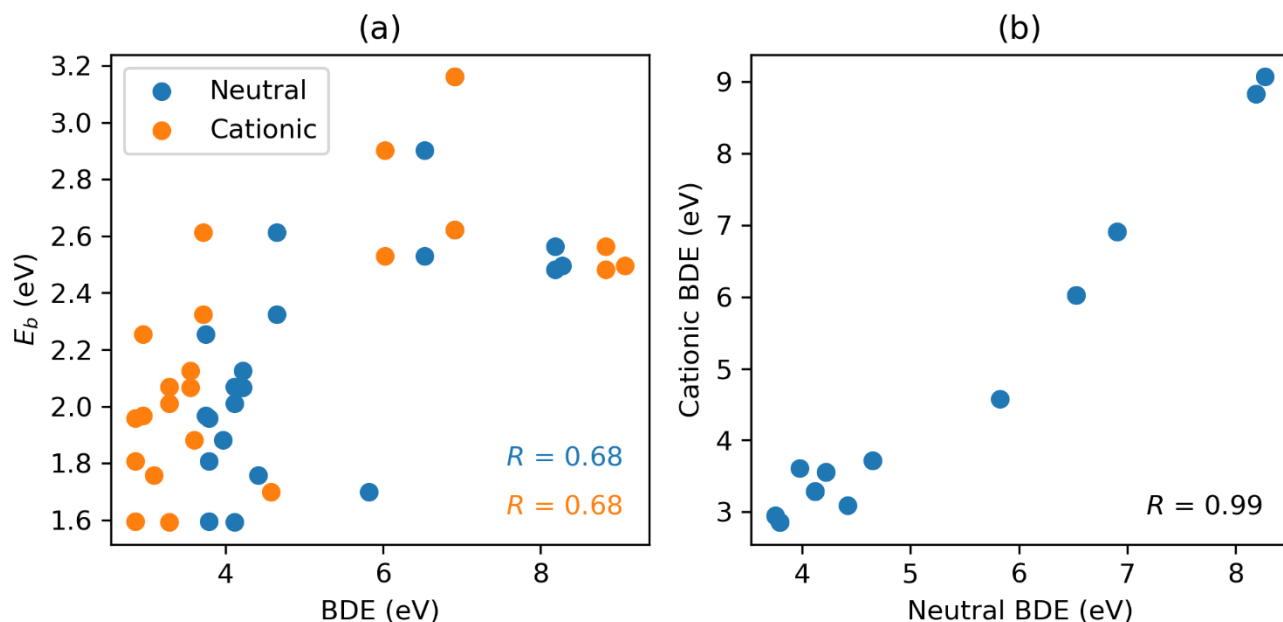

**Figure S7.** Effect of crystal system on  $E_v$  where M, O, T, R, H, and C are monoclinic, orthorhombic, tetragonal, rhombohedral, hexagonal, and cubic, respectively. Error bars show the standard deviation of  $E_v$ . All data are shown on the left whereas the data are collated by B-cation on the right (averages are shown as vertices along each crystal system axis). The left panel shows that no direct correlation exists between crystal system and  $E_v$ . On the other hand, **Figure 6** in the main text shows a strong correlation between  $E_b$ ,  $V_r$ , and  $E_v$ . Since **Equations 2** and **5** in the main text indicate that  $E_b$  and  $V_r$  are structure independent while **Equation 9** in the main text reveals that  $V_r$  typically is that of the B-site cation, we

also sorted by B-site cation (right panel) to uncover any further correlations. Still, only a weak, direct correlation is evident between crystal system and  $E_v$  in the right panel (given by the degree of distortion away from a regular hexagon). Given that the two other descriptors in our model,  $E_g$  and  $E_{hull}$ , are indeed structure dependent, it appears that a weak, indirect correlation exists between crystal system and  $E_v$  via  $E_g$  and  $E_{hull}$ .

**Table S2.** Theoretical and experimental cohesive energies ( $E_c$ ) across all metal oxides considered.

Metal oxide	SCAN+U $E_c$ (eV)	Exp <sup>3-6</sup> $E_c$ (eV)	Relative error (eV)
CaO	11.30	11.00	0.30
SrO	10.54	10.44	0.11
BaO	10.20	10.22	-0.02
La <sub>2</sub> O <sub>3</sub>	34.94	35.28	-0.33
Ce <sub>2</sub> O <sub>3</sub>	34.74	35.27	-0.53
CeO <sub>2</sub>	20.51	20.78	-0.27
TiO <sub>2</sub>	18.96	19.81	-0.84
VO <sub>2</sub>	17.41	17.87	-0.46
CrO <sub>2</sub>	15.68	15.30	0.38
MnO <sub>2</sub>	13.52	13.48	0.05
FeO <sub>2</sub>	12.75	n/a	n/a
CoO <sub>2</sub>	12.07	n/a	n/a
NiO <sub>2</sub>	11.76	n/a	n/a
Ti <sub>2</sub> O <sub>3</sub>	31.46	33.21	-1.75
V <sub>2</sub> O <sub>3</sub>	30.34	31.00	-0.66
Cr <sub>2</sub> O <sub>3</sub>	27.88	27.66	0.22
Mn <sub>2</sub> O <sub>3</sub>	23.62	23.51	0.11
Fe <sub>2</sub> O <sub>3</sub>	24.80	24.82	-0.02
Co <sub>3</sub> O <sub>4</sub>	33.12	32.88	0.23
Ni <sub>2</sub> O <sub>3</sub>	21.68	21.70	-0.02
CoO	9.56	9.45	0.11
NiO	9.57	9.52	0.05

**Figure S8.** (a) Correlation of experimental bond dissociation energies (BDEs) for neutral diatomic molecules (blue) and diatomic cations (orange) with respect to SCAN+ $U$ -calculated crystal bond dissociation energies ( $E_b$ ) showing the difference between molecular and crystal bond strengths.  $R$  is the Pearson correlation coefficient.<sup>7</sup> (b) Experimental BDEs for neutral diatomic molecules strongly correlate with those of diatomic cations. We tabulated BDEs and  $E_b$  in features.csv.

**Figure S9.** Specific trends in the SCAN+ $U$ -calculated and experimental  $V_r$  vs. (a) A-site atoms (+2/+3/+4), (b) B-site atoms with +4 oxidation state, (c) B with +3, and (d) B with +2. Experimental  $V_r$  for  $FeO_2$ ,  $CoO_2$ , and  $NiO_2$  are not available due to the metastability of binary  $Fe^{4+}$ ,  $Co^{4+}$ , and  $Ni^{4+}$  oxides. We tabulated  $V_r$  in features.csv.

**Figure S10.** SCAN+U-calculated vs. simplified-model-predicted  $E_v$  for (a) room-temperature-stable ( $E_{hull} \leq 298.15k_B$ ) and (b) all  $ABO_3$  perovskite structures considered.
