Scientific journey so far...

Solar thermochemical (STC) production of H₂ and/or CO

Candidates so far:

- CeO₂
- Fe(Fe,X)₂O₄
- (A,A')BO₃

Thermal reduction (TR)
High T (> 1473 K)
~vacuum ($p_{O_2} < 100$ Pa)

Water splitting (WS)
Low T (873-1073 K)
High H₂ yield ($\frac{p_{H_2O}}{p_{H_2}} = 9$)

State-of-the-art:
Pure and doped
fluorite-CeO₂

Needs “good” materials!

- Durability (withstand high TR and low WS temperatures)
- Capacity (tolerate high degrees of oxygen off-stoichiometry)
- Stability (no undesired phase transformations)

New candidates?

Solar thermochemical (STC) production of H₂ and/or CO

Candidates so far:

- CeO₂
- Fe(Fe,X)₂O₄
- (A,A')BO₃

German research center (DLR), 2017

State-of-the-art:
Pure and doped
fluorite-CeO₂

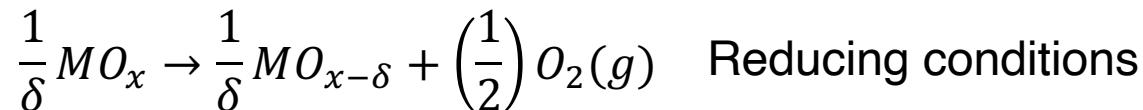

Needs “good” materials!

- Durability (withstand high TR and low WS temperatures)
- Capacity (tolerate high degrees of oxygen off-stoichiometry)
- Stability (no undesired phase transformations)

New candidates?

Siegel *et al.*, Ind. Eng. Chem. Res. 2013, 52, 3276
Carillo and Scheifele, Sol. Energy 2017, 156, 3

Enthalpy of reduction = spontaneity

Enthalpy of reduction for the induced off-stoichiometry, δ

$$\Delta H_{reduction} = \frac{H_{MO_{x-\delta}} - H_{MO_x}}{\delta} + \left(\frac{1}{2}\right) H_{O_2}(g)$$

If $\delta \rightarrow 0$, then

$$\Delta H_{reduction} = - \frac{dH_{MO_x}}{dx} \Big|_x + \left(\frac{1}{2}\right) H_{O_2}(g) \equiv \Delta H_{formation}^{Vao} \quad \text{Oxygen vacancy formation energy (Calculable)}$$

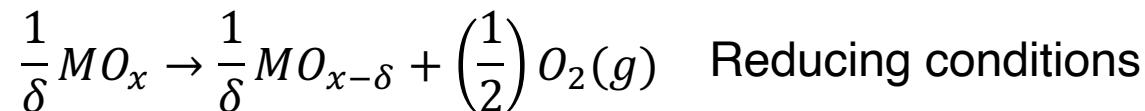

Low $\Delta H_{reduction}$ = large δ

But induced δ needs to be recovered during water-splitting (re-oxidation) \rightarrow optimal $\Delta H_{reduction}$

Thermodynamic models¹ point to optimal $\Delta H_{reduction}$ or $\Delta H_{formation}^{Vao} \sim 3.4\text{-}3.9 \text{ eV}$ (CeO_2 is $\sim 4 \text{ eV}$)

Theoretical screening purposes: 3.2-4.1 eV ($\pm 0.2 \text{ eV}$ error)

Enthalpy of reduction = spontaneity

Enthalpy of reduction for the induced off-stoichiometry, δ

$$\Delta H_{reduction} = \frac{H_{MO_{x-\delta}} - H_{MO_x}}{\delta} + \left(\frac{1}{2}\right) H_{O_2}(g)$$

Several studies have theoretically screened, high-throughput calculations and/or machine learning, for novel ABO_3 perovskites, based on a $\Delta H_{formation}^{Vao}$ range

- Candidates either exhibit rare elements (e.g., Eu, Ho) or don't exceed CeO_2 's performance in experiments (stability or kinetic limitations or theory error)
- Entropic handles? Beyond ternary ABO_3 candidates?

Thermodynamic models¹ point to optimal $\Delta H_{reduction}$ or $\Delta H_{formation}^{Vao} \sim 3.4\text{-}3.9$ eV (CeO_2 is ~ 4 eV)
Theoretical screening purposes: 3.2-4.1 eV (± 0.2 eV error)

Higher entropy of reduction = higher productivity

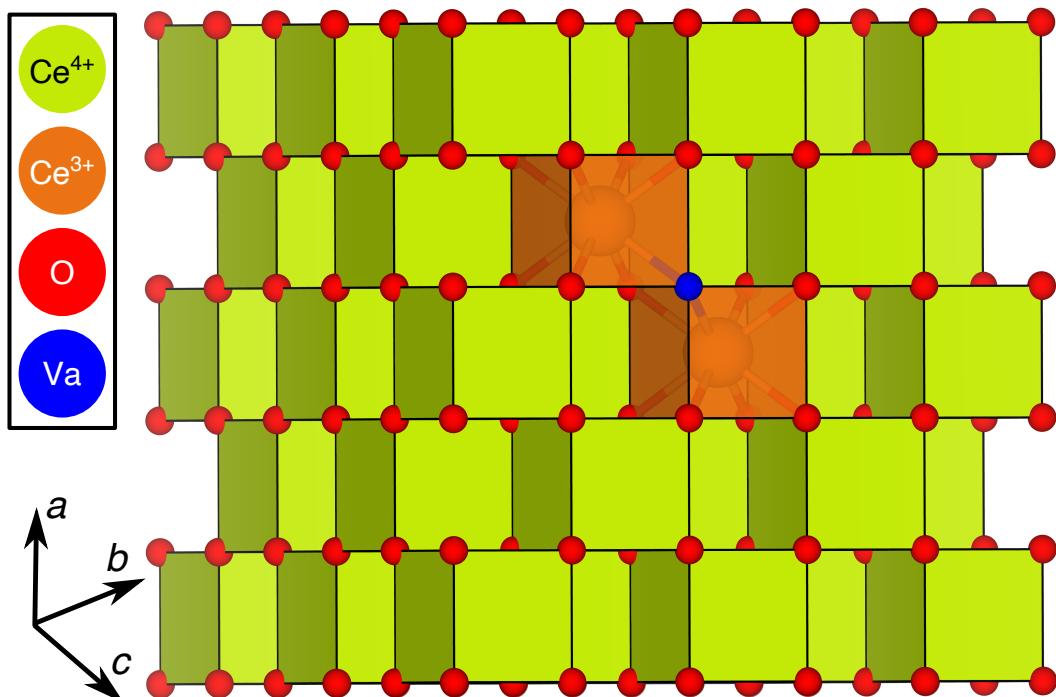

Entropy of reduction for an induced off-stoichiometry, δ , in ABO_3

$$\Delta S_{reduction} = \frac{S_{ABO_3-\delta} - S_{ABO_3}}{\delta} + \left(\frac{1}{2}\right) S_{O_2}(g)$$

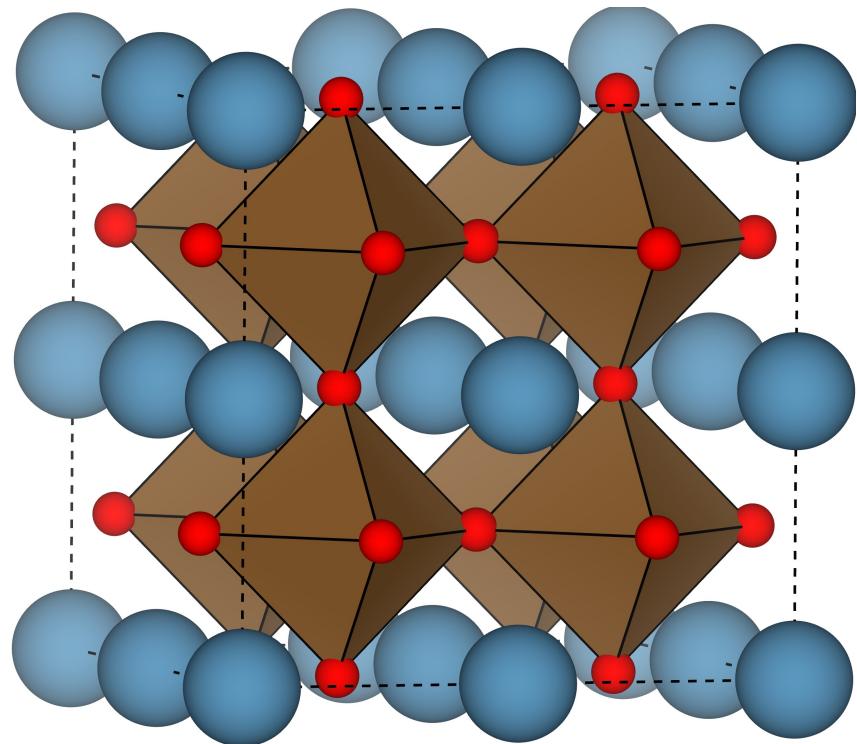

solid gas

Not easily calculable

Higher $\Delta S_{reduction}$ → stabilizes large δ → can result in higher H₂/mol oxide

Ce sub-lattice + O sub-lattice configurational S

B sub-lattice + O sub-lattice

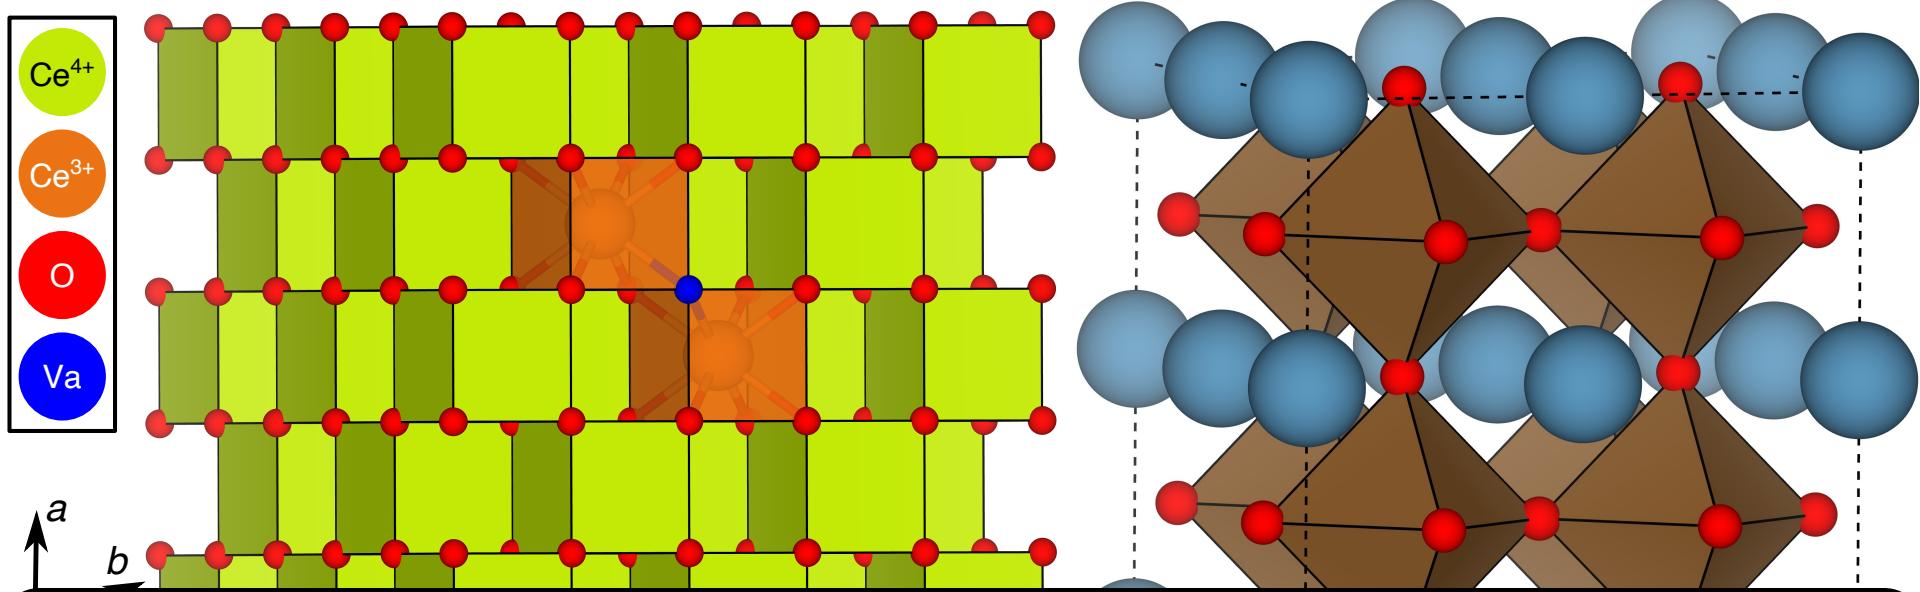

Higher entropy of reduction = higher productivity

Entropy of reduction for an induced off-stoichiometry, δ , in ABO_3

$$\Delta S_{reduction} = \frac{S_{ABO_3-\delta} - S_{ABO_3}}{\delta} + \left(\frac{1}{2}\right) S_{O_2}(g)$$

solid	gas	Not easily calculable
-------	-----	-----------------------

Higher $\Delta S_{reduction}$ → stabilizes large δ → can result in higher H₂/mol oxide

The lack of redox-activity of A in ABO_3 reduces configurational entropy (per O) in ABO_3 vs. CeO_2

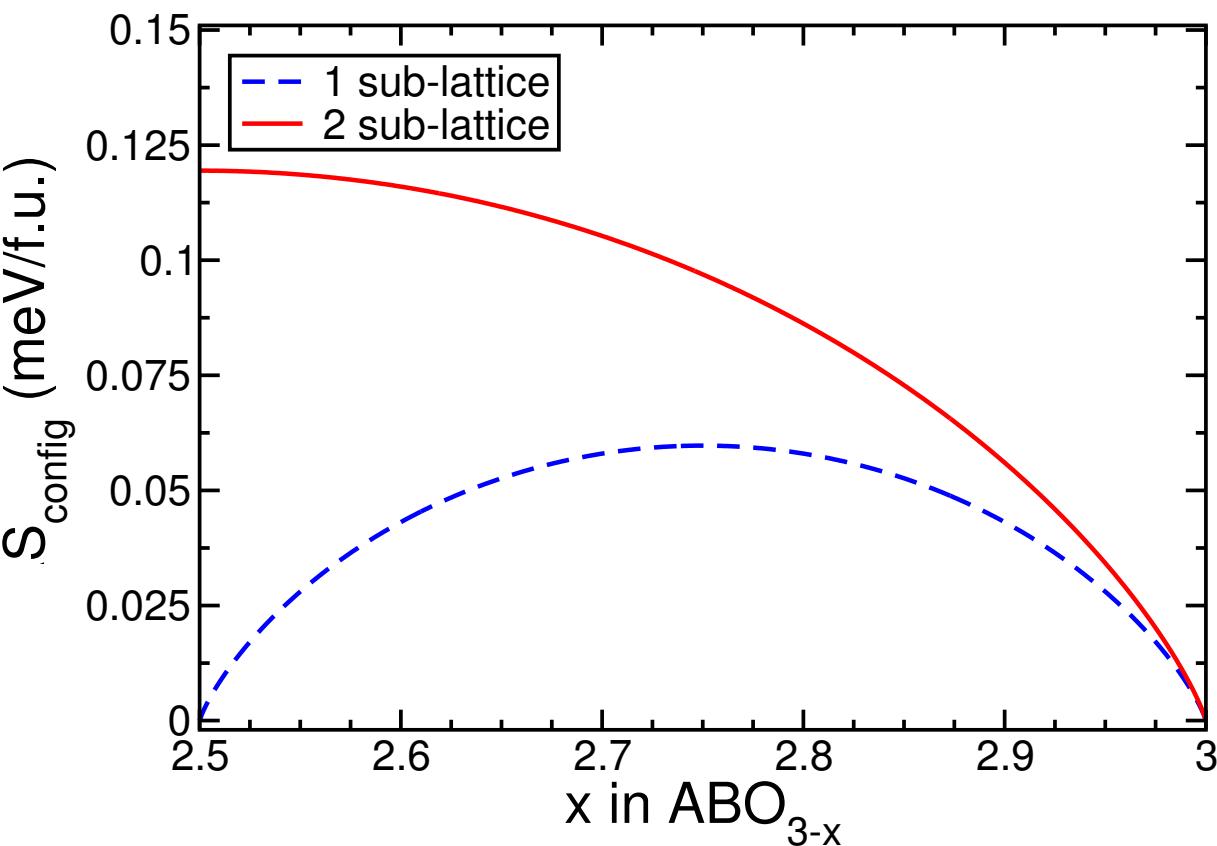

- If A is redox-active in addition to B: ABO_3 's configurational entropy can increase beyond CeO_2
- Will productivity gains be worth it? How to quantify?

Simultaneous redox-activity = higher productivity

Entropy of reduction for an induced off-stoichiometry, δ , in ABO_3

$$\Delta S_{reduction} = \frac{S_{ABO_3-\delta} - S_{ABO_3}}{\delta} + \left(\frac{1}{2}\right) S_{O_2}(g)$$

solid	gas	Not easily calculable
-------	-----	-----------------------

Larger configurational entropy of reduction in 2 sub-lattice (simultaneous reduction) than 1 sub-lattice (single reduction) in ABO_3

$$S_{config} (1 \text{ sub-lattice}, \text{ABO}_x) = -k_B \left((6 - 2x) \ln(6 - 2x) + (2x - 5) \ln(2x - 5) \right)$$

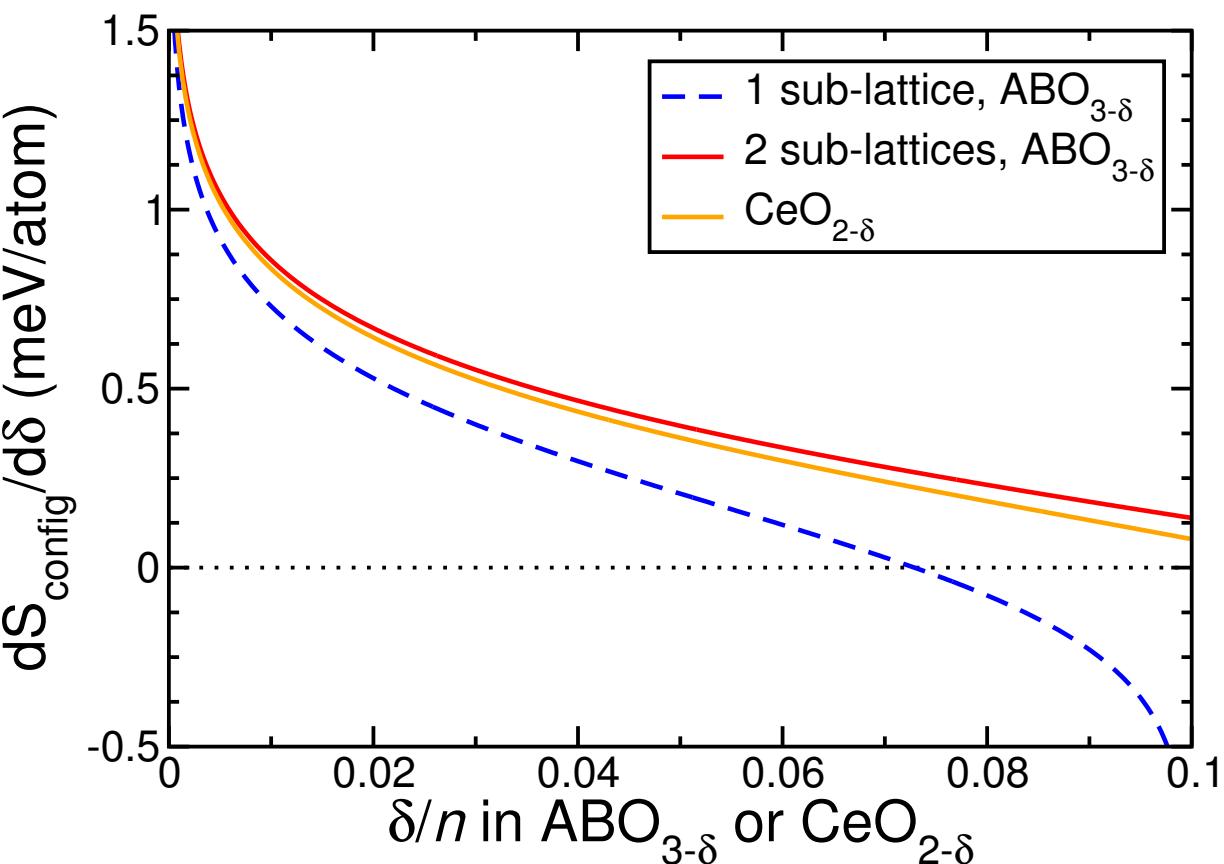

$$S_{config}(2 \text{ sub-lattices}, \text{ABO}_x) = -k_B((3-x) \ln(3-x) + (x-2) \ln(x-2))$$

Simultaneous redox-activity = higher productivity

Entropy of reduction for an induced off-stoichiometry, δ , in ABO_3

$$\Delta S_{reduction} = \frac{S_{ABO_3-\delta} - S_{ABO_3}}{\delta} + \left(\frac{1}{2}\right) S_{O_2}(g)$$

solid	gas	Not easily calculable
-------	-----	-----------------------

Equilibrium oxygen off-stoichiometry (δ_{eq}) is determined by oxygen chemical potential (μ_O) for given reduction/re-oxidation conditions

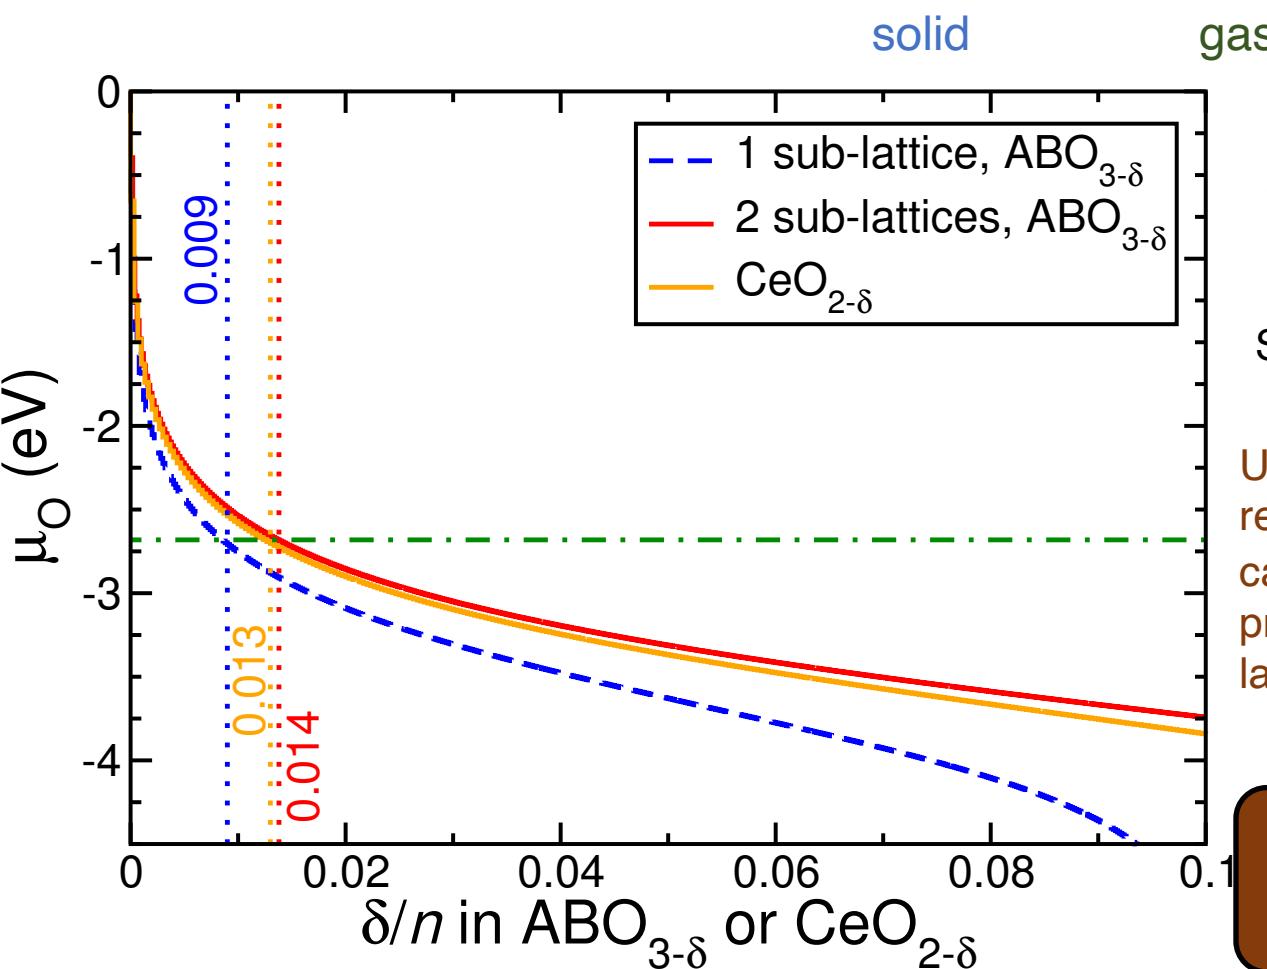

$$\mu_O \propto \frac{dS_{config}}{d\delta} \approx f[\ln\left(\frac{\delta}{1-\delta}\right)]$$

Differential of configurational entropy in 2 sub-lattice ABO_3 has a less-steep decline than CeO_2

Simultaneous redox-activity = higher productivity

Entropy of reduction for an induced off-stoichiometry, δ , in ABO_3

$$\Delta S_{reduction} = \frac{S_{ABO_3-\delta} - S_{ABO_3}}{\delta} + \left(\frac{1}{2}\right) S_{O_2}(g) \quad \text{Not easily calculable}$$

$$\mu_O \approx \Delta H_{formation}^{Va_O} + T \frac{dS_{config}}{d\delta}$$

Set same $\Delta H_{formation}^{Va_0}$ = CeO_{2-δ}

Under given enthalpy of reduction, T and p_{O_2} , 2 sub-lattice can yield 9% and 46% higher productivity than CeO_2 and 1 sub-lattice

Any perovskites with simultaneous redox-activity?

Structural constraints: ABO_3 can allow (A,B) to be redox-active simultaneously, but...

Difficult to describe redox + not common in oxide perovskite

Explore Ca-Ce-M-O perovskites ($M = 3d$ except Cu, Zn) for potential simultaneous redox activity

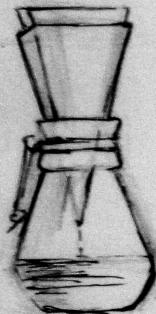

- Specifically, look at $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{MO}_3$ using theoretical calculations
- Still need to have ideal ΔH !
- And be thermodynamically stable

Not as many options for cations on A site that can be redox active (and reasonably abundant)

- Ce (+4/+3)

Ca most compatible with Ce on A (1.12 Å ionic radius vs. 0.97-1.14 Å)

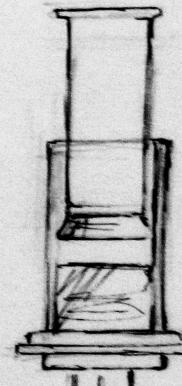

BREW METHODS

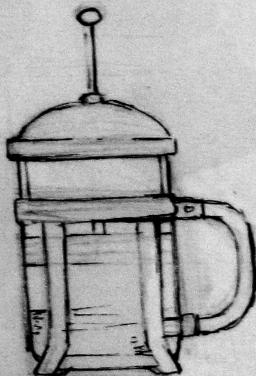

CHEMEX

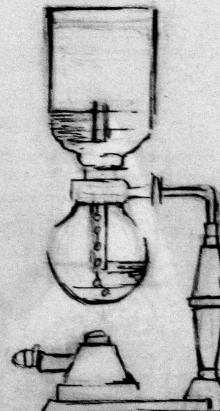

FLAT BOTTOM
POUR OVER FILTER

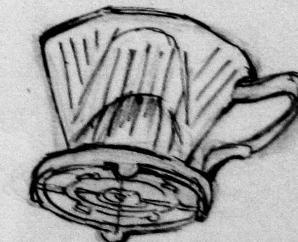

AEROPRESS

FRENCH PRESS

SYPHON

CLEVER DRIPPER

Methods detour: calculation
setup, structural input and stability

Density functional theory (DFT): predict material properties

$$H\psi = E\psi \longrightarrow \text{Total energy at } 0 \text{ K} \approx \text{Gibbs energy} \rightarrow \text{Thermodynamics}$$

Density of states + Band structure → Band gap

Energy to displace atoms → Phonon/vibrational

Barriers for atomic migration → Kinetics

Energy of defective structures → Defect thermodynamics

Density functional theory^{1,2}: approximate electronic interactions into a non-interacting mean-field

- Approximation: exchange-correlation (XC) functional

DFT toolkit choice: Vienna ab initio simulation package
(<https://www.vasp.at/>)

XC functionals: Jacob's ladder of increasing accuracy

- Choice: strongly constrained appropriately normed (SCAN)³

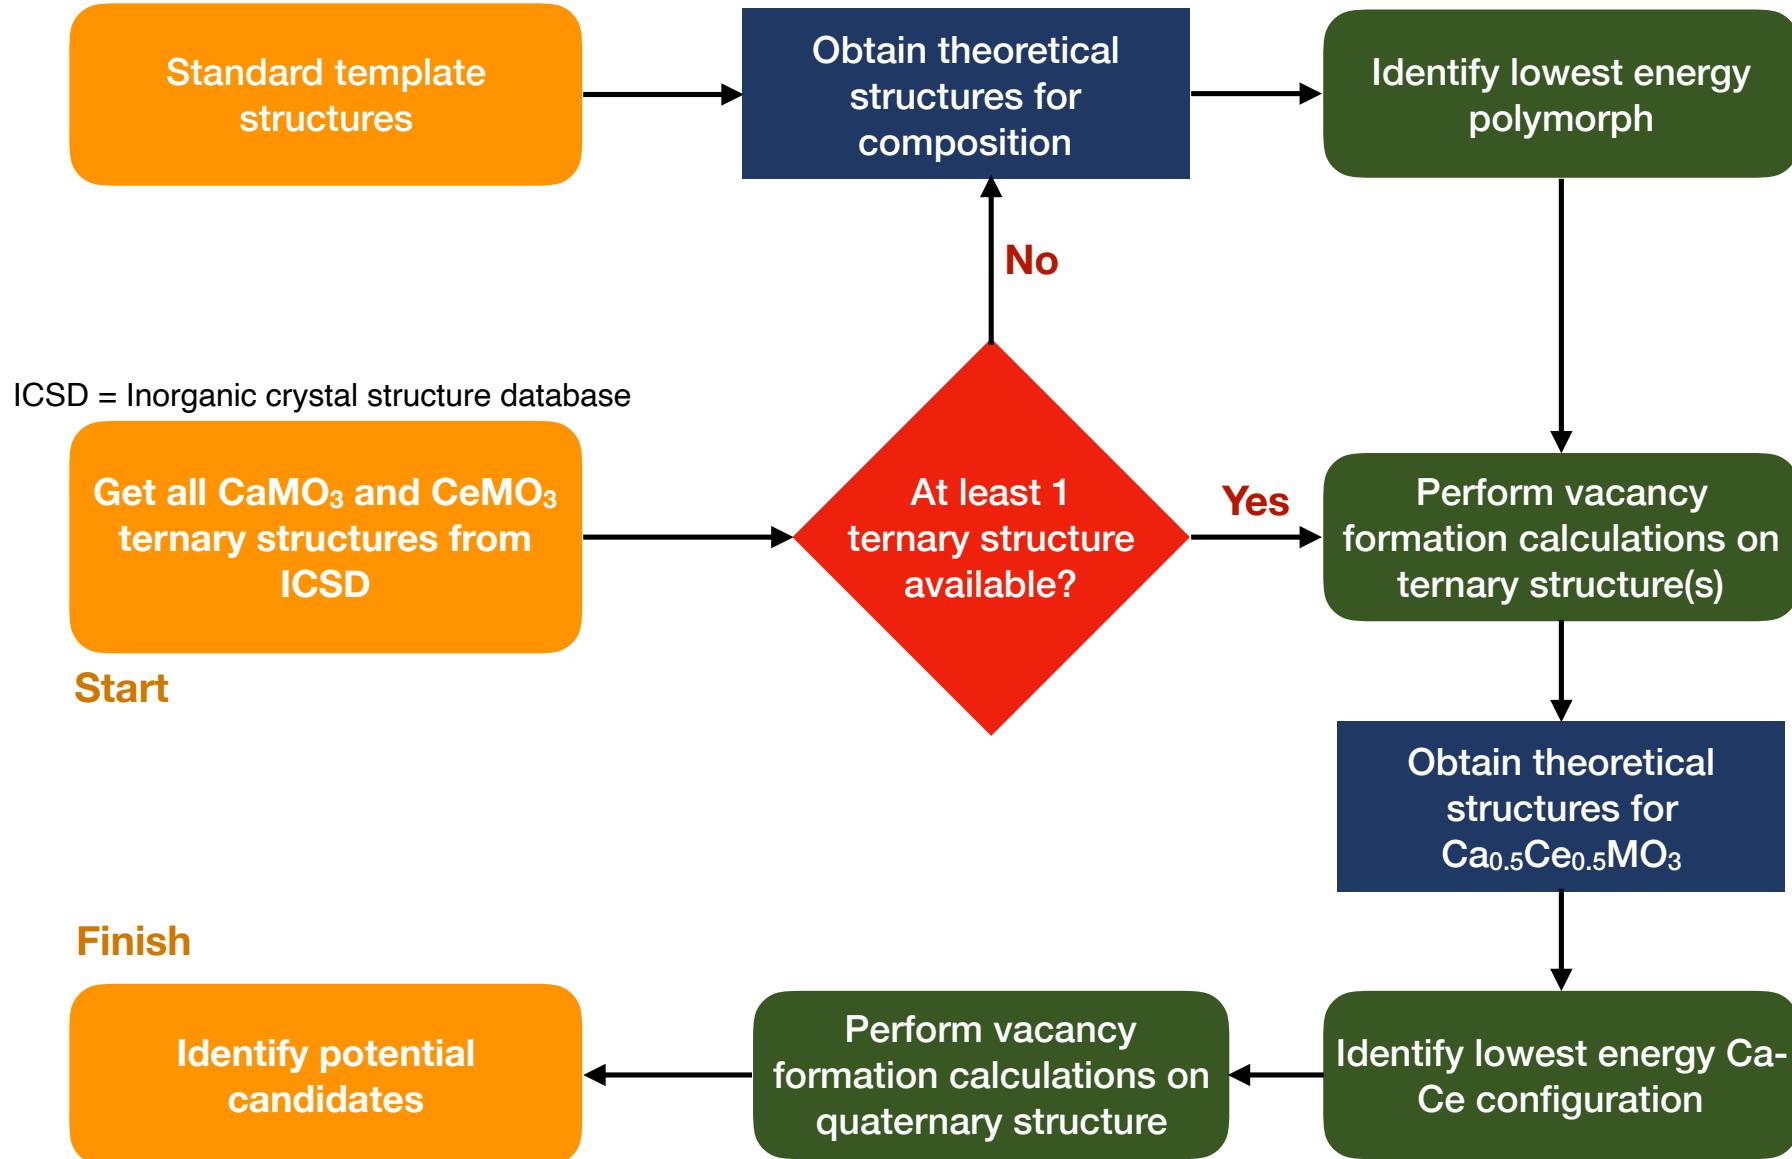

Need structural input!

2. Kohn and Sham, *Phys. Rev.* 1965, 140, A1133

No experimental $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{MO}_3$ structures available: use CaMO_3 or CeMO_3

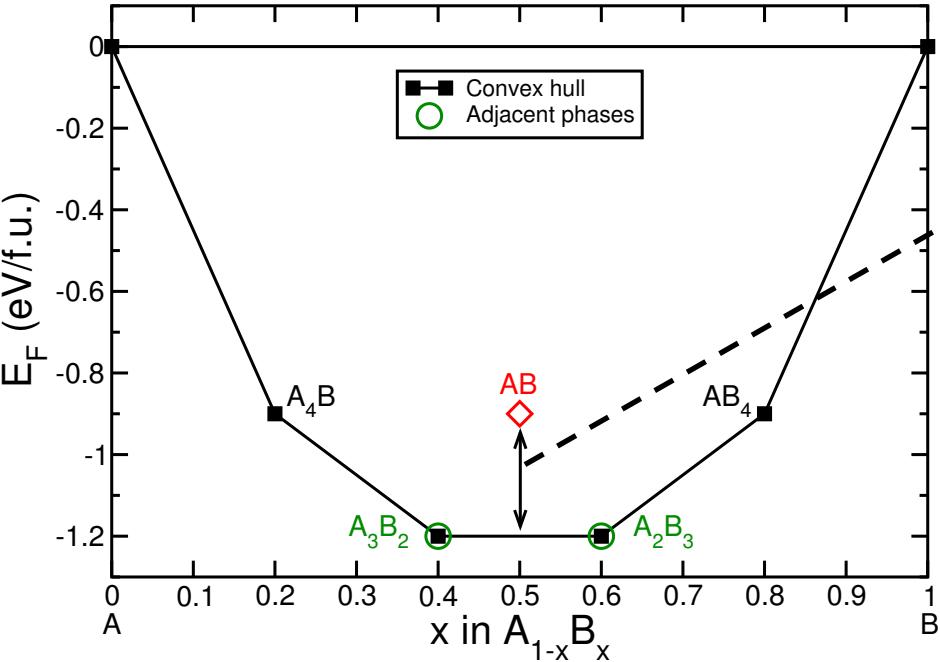

Templating scheme for theoretical (Co & Ni) structures

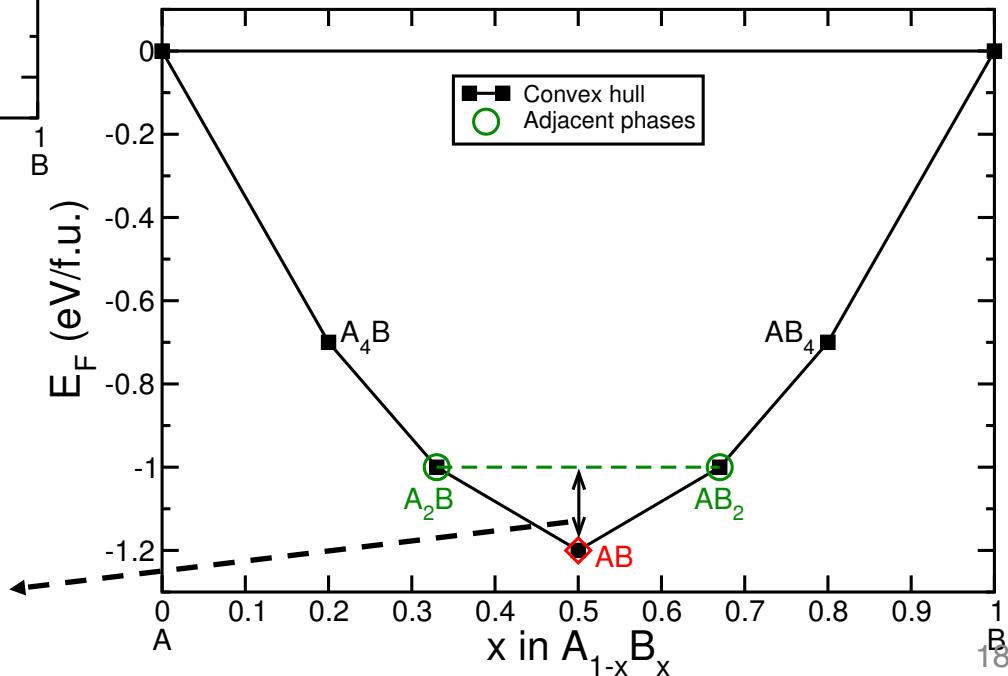

0 K thermodynamics: convex hull

E^{hull} : measure of stability of given structure+composition combination (at 0 K)

Positive E^{hull} : metastable (< 25-50 meV/atom) or unstable (>50 meV/atom)

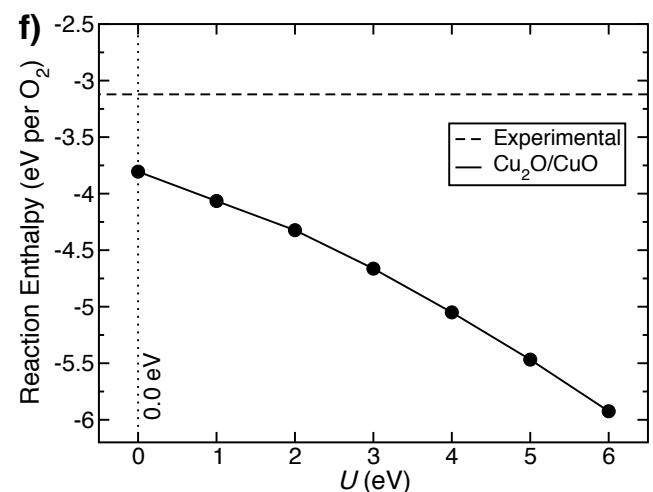

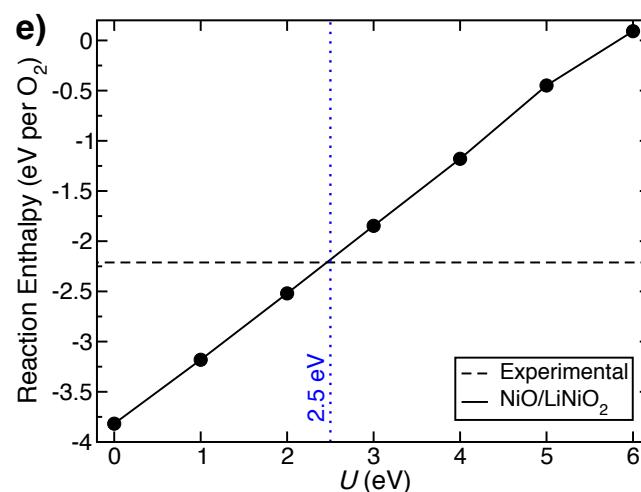

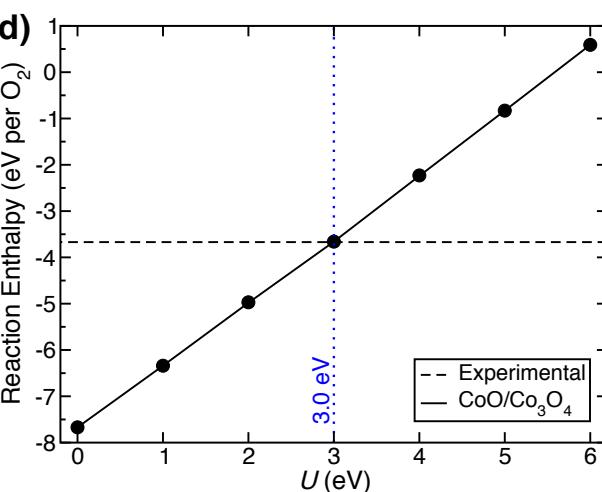

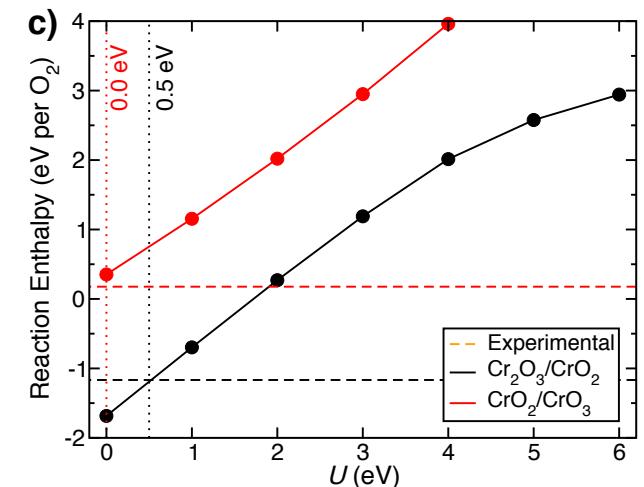

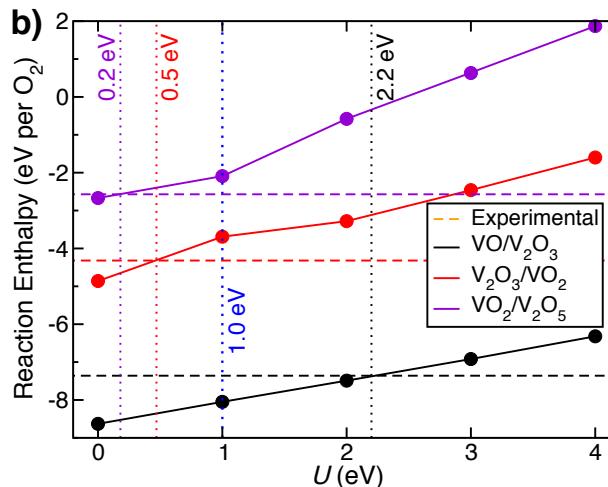

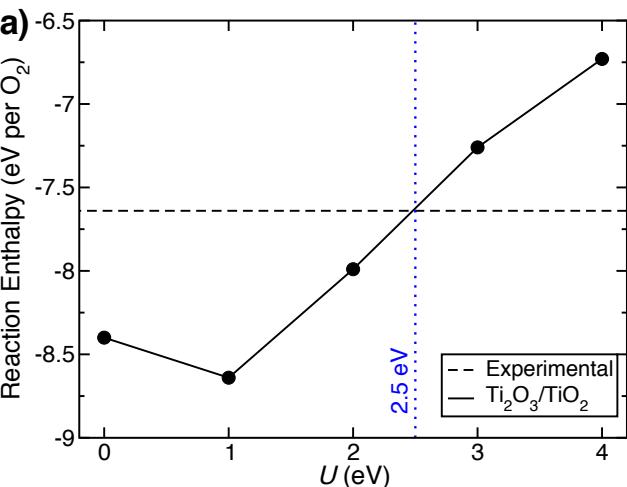

- Largest energy release via decomposition of AB

Negative E^{hull} : stable

- Lowest energy release via formation of AB

XC functional: a U correction to SCAN

$$U_{\text{Mn}} = 2.7 \text{ eV}$$

$$U_{\text{Fe}} = 3.1 \text{ eV}$$

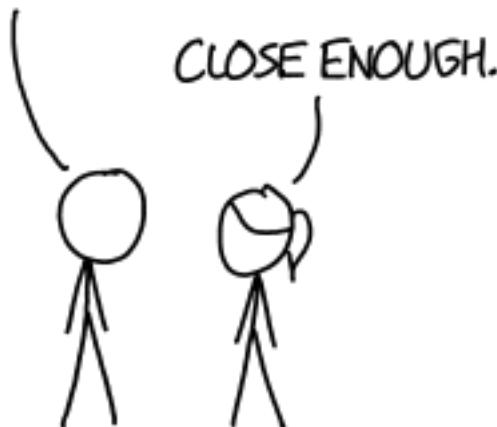

$$U_{\text{Ce}} = 2.0 \text{ eV}$$

$$U_{\text{Sc}} = 0.0 \text{ eV}$$

Convex hull at 0 K: SCAN+ U including all binary, ternary, and quaternary ICSD structures

$$\Delta H_{\text{reduction}} \approx E_F[\text{Va}_0]$$

THE SECOND LAW OF THERMODYNAMICS STATES
THAT A ROBOT MUST NOT INCREASE ENTROPY,
UNLESS THIS CONFLICTS WITH THE FIRST LAW.

Results

Ternaries

- Structures
- Vacancy formation
- Stability

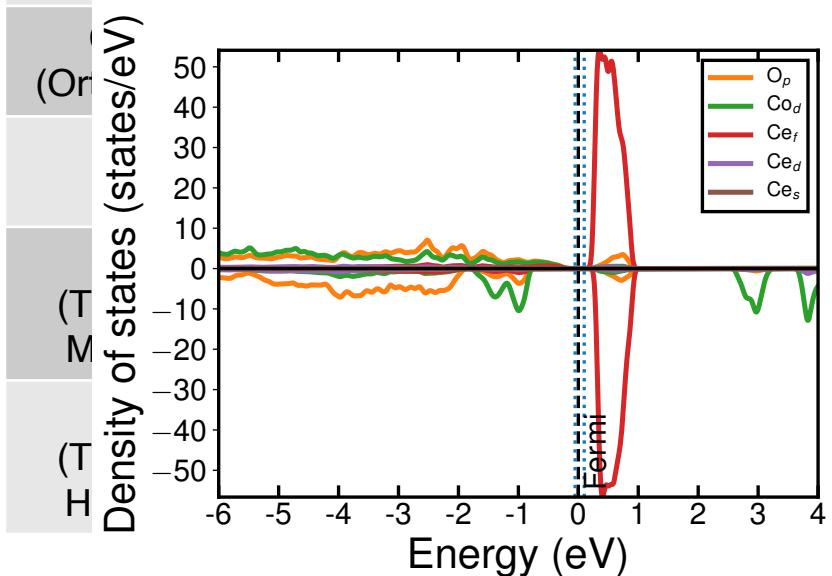

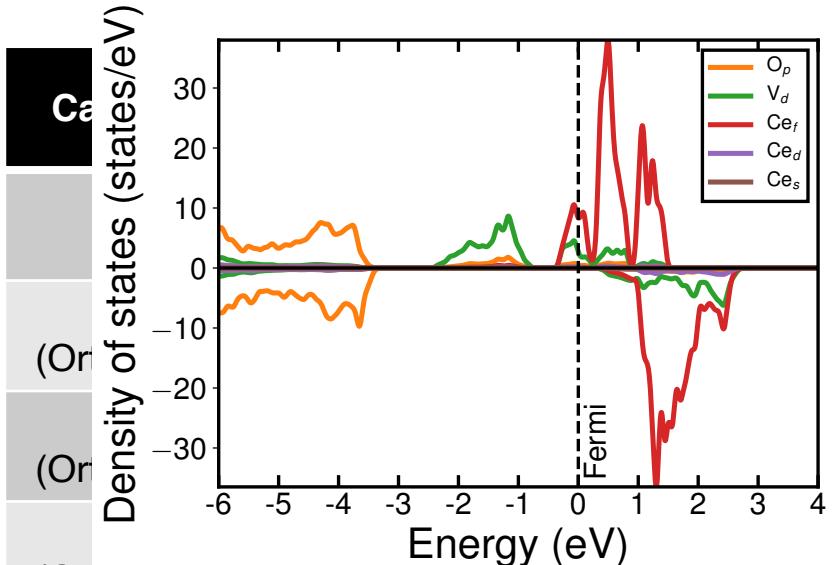

Quaternaries

- Vacancy formation
- Stability

Structures and oxidation states: CaMO₃ and CeMO₃

Ca-ternaries	Ca	M	Ce-ternaries	Ce	M
CaScO ₃	—		CeScO ₃ (Orthorhombic)	+3	+3
CaTiO ₃ (Orthorhombic)			CeTiO ₃	—	
CaVO ₃ (Orthorhombic)			CeVO ₃ (Monoclinic)	+3	+3
CaCrO ₃ (Orthorhombic)			CeCrO ₃ (Cubic)		
CaMnO ₃ (Orthorhombic)	+2	+4	CeMnO ₃	—	
CaFeO ₃			CeFeO ₃		
CaCoO ₃ (Theoretical, Monoclinic)			CeCoO ₃ (Theoretical, Orthorhombic)	+4	+2
CaNiO ₃ (Theoretical, Hexagonal)			CeNiO ₃ (Theoretical, Monoclinic)		

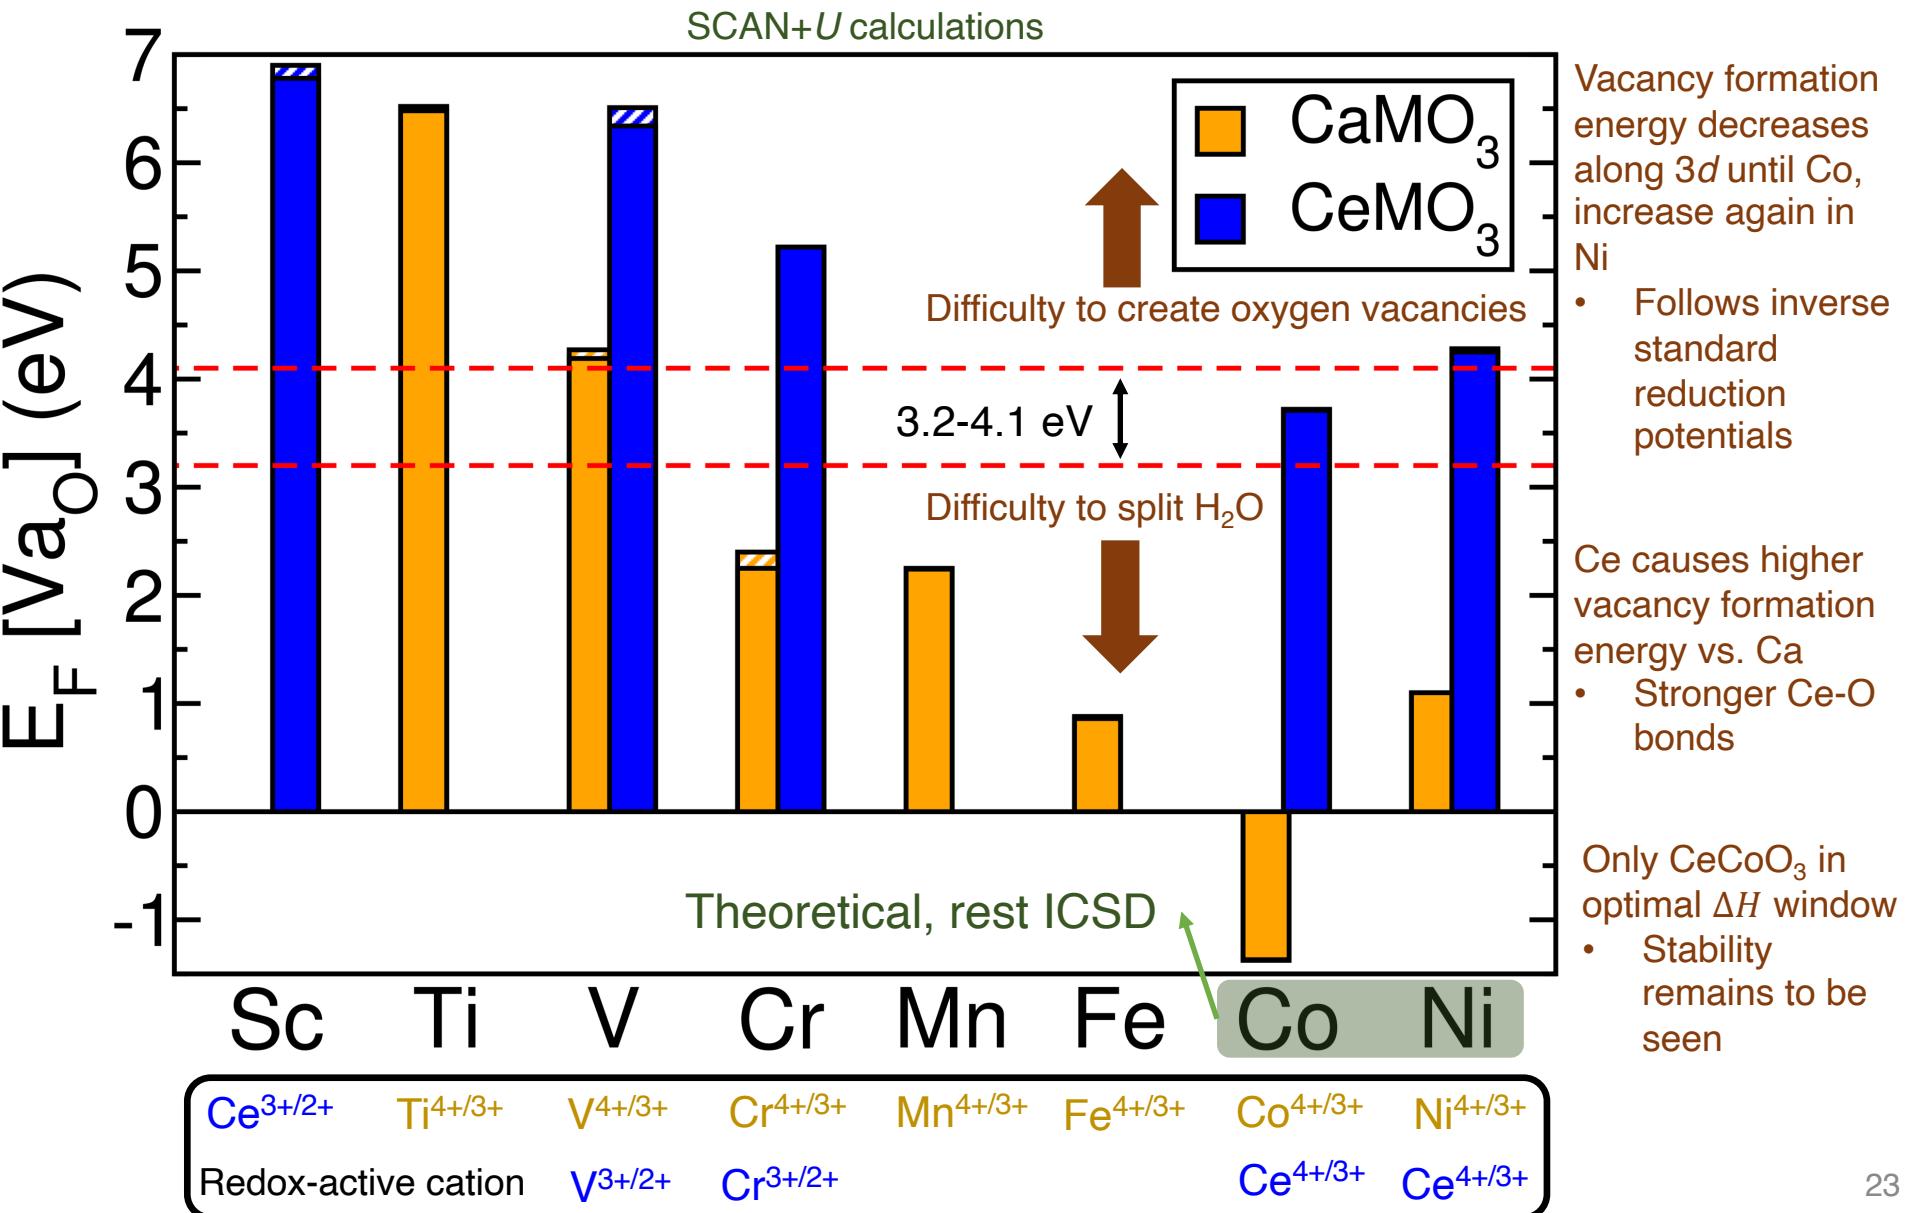

Structures and oxidation states: CaMO_3 and CeMO_3

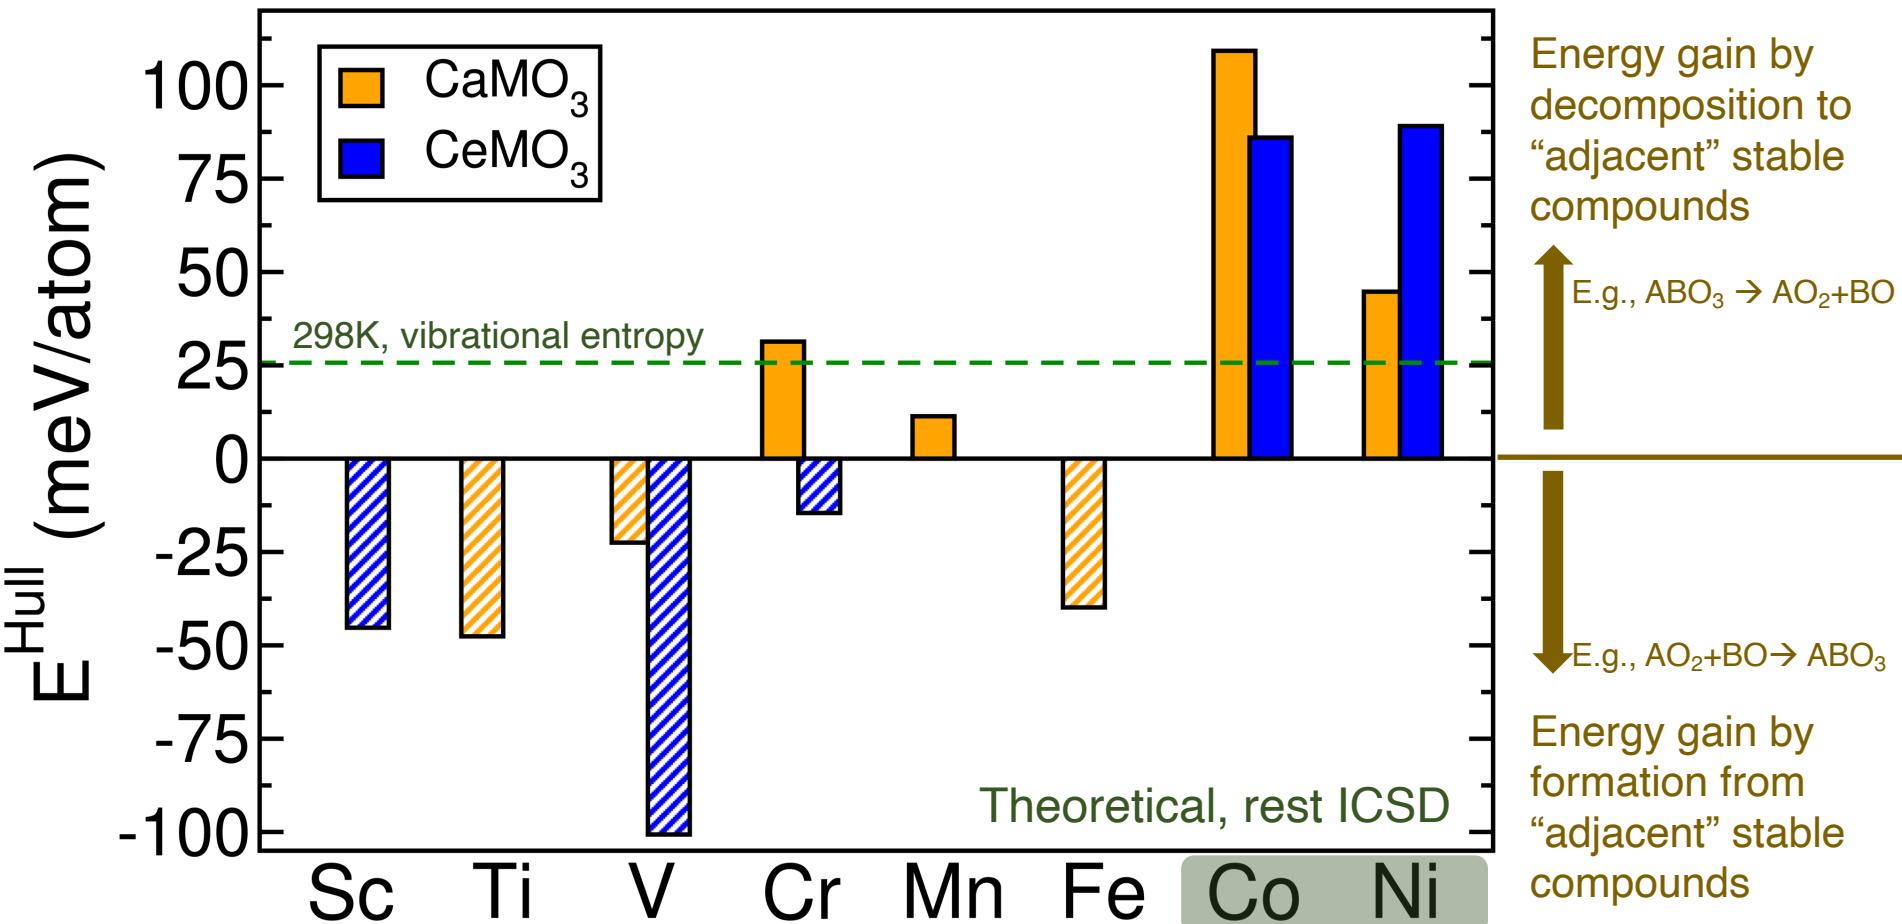

Ca	Ce-ternaries	Ce	M
(Or)	CeScO_3 (Orthorhombic)	+3	+3
(Or)	CeTiO_3	-	
(Orthorhombic)	CeVO_3 (Monoclinic)	+3	+3
(Or)	CeCrO_3 (Cubic)		
(Or)	CeMnO_3		
(T)	CeFeO_3	-	
(T)	CeCoO_3 (Theoretical, Orthorhombic)	+4	+2
H	CeNiO_3 (Theoretical, Monoclinic)		

Based on on-site magnetic moments and/or density of states

Oxygen vacancy formation in CaMO_3 and CeMO_3 : no obvious candidate

0 K stability: CaMO_3 and CeMO_3

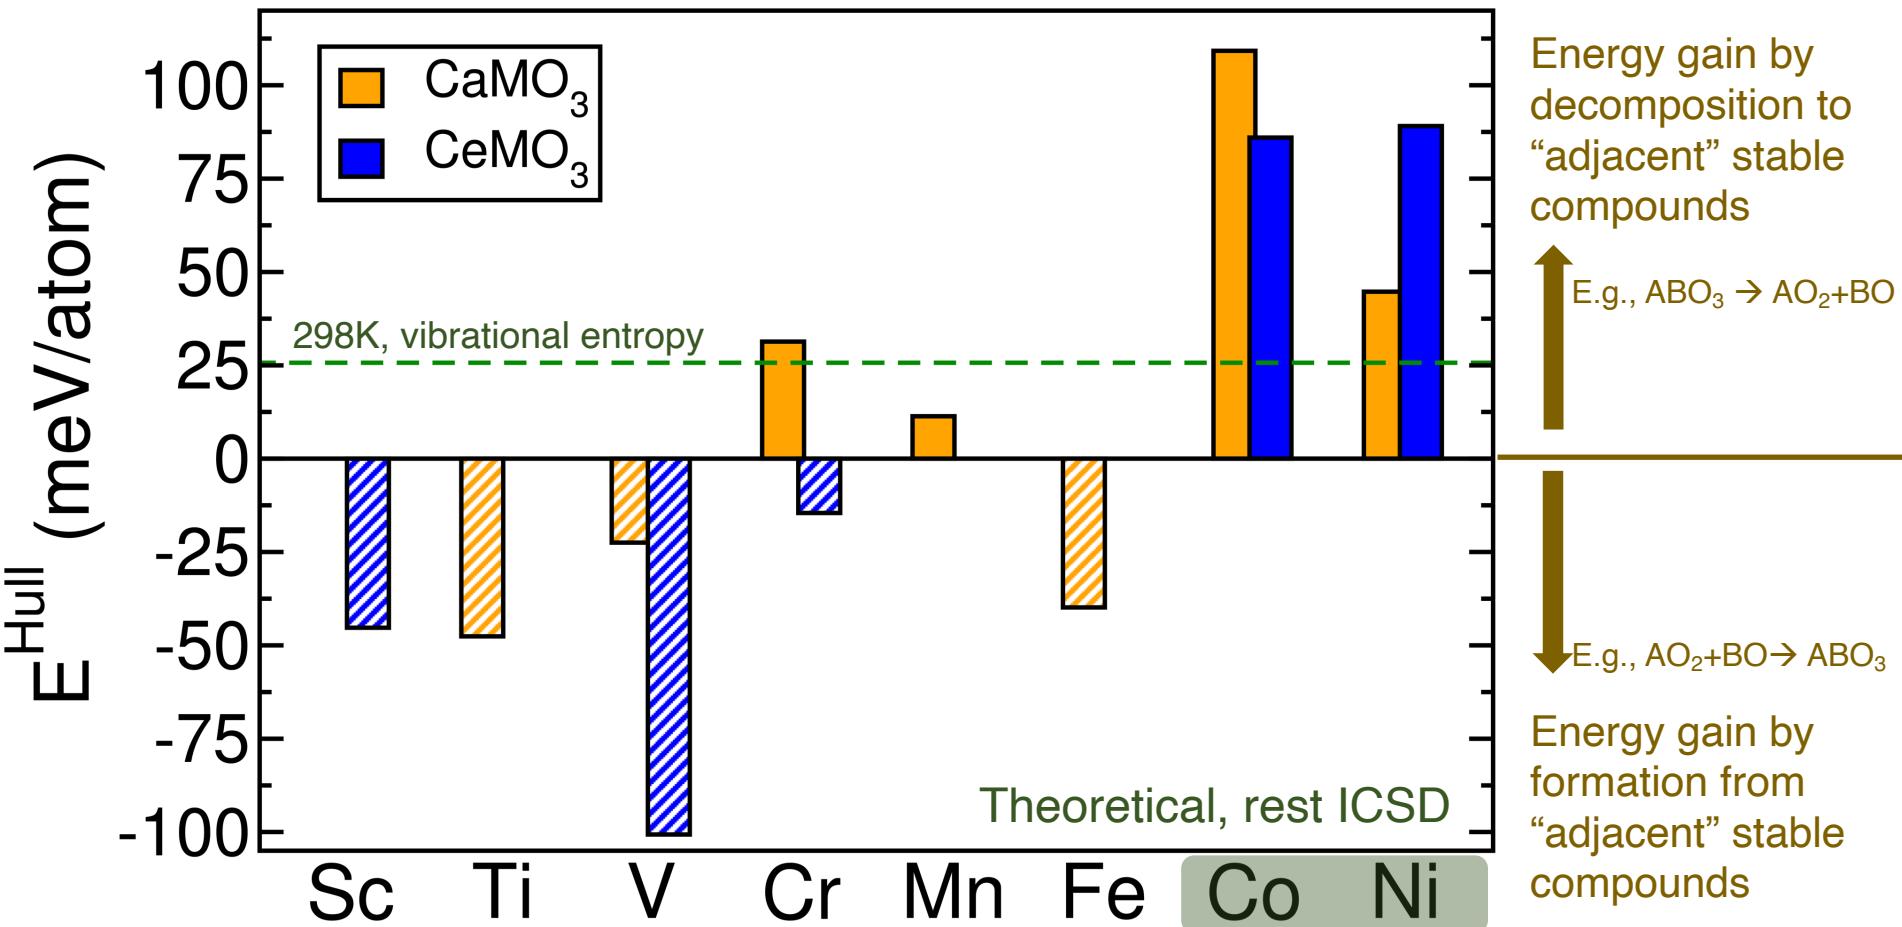

ICSD structures: either negative E_{hull} or small positive E_{hull}

Theoretical structures: large positive E_{hull}

Weak correlation between negative E_{hull} and large vacancy formation energy

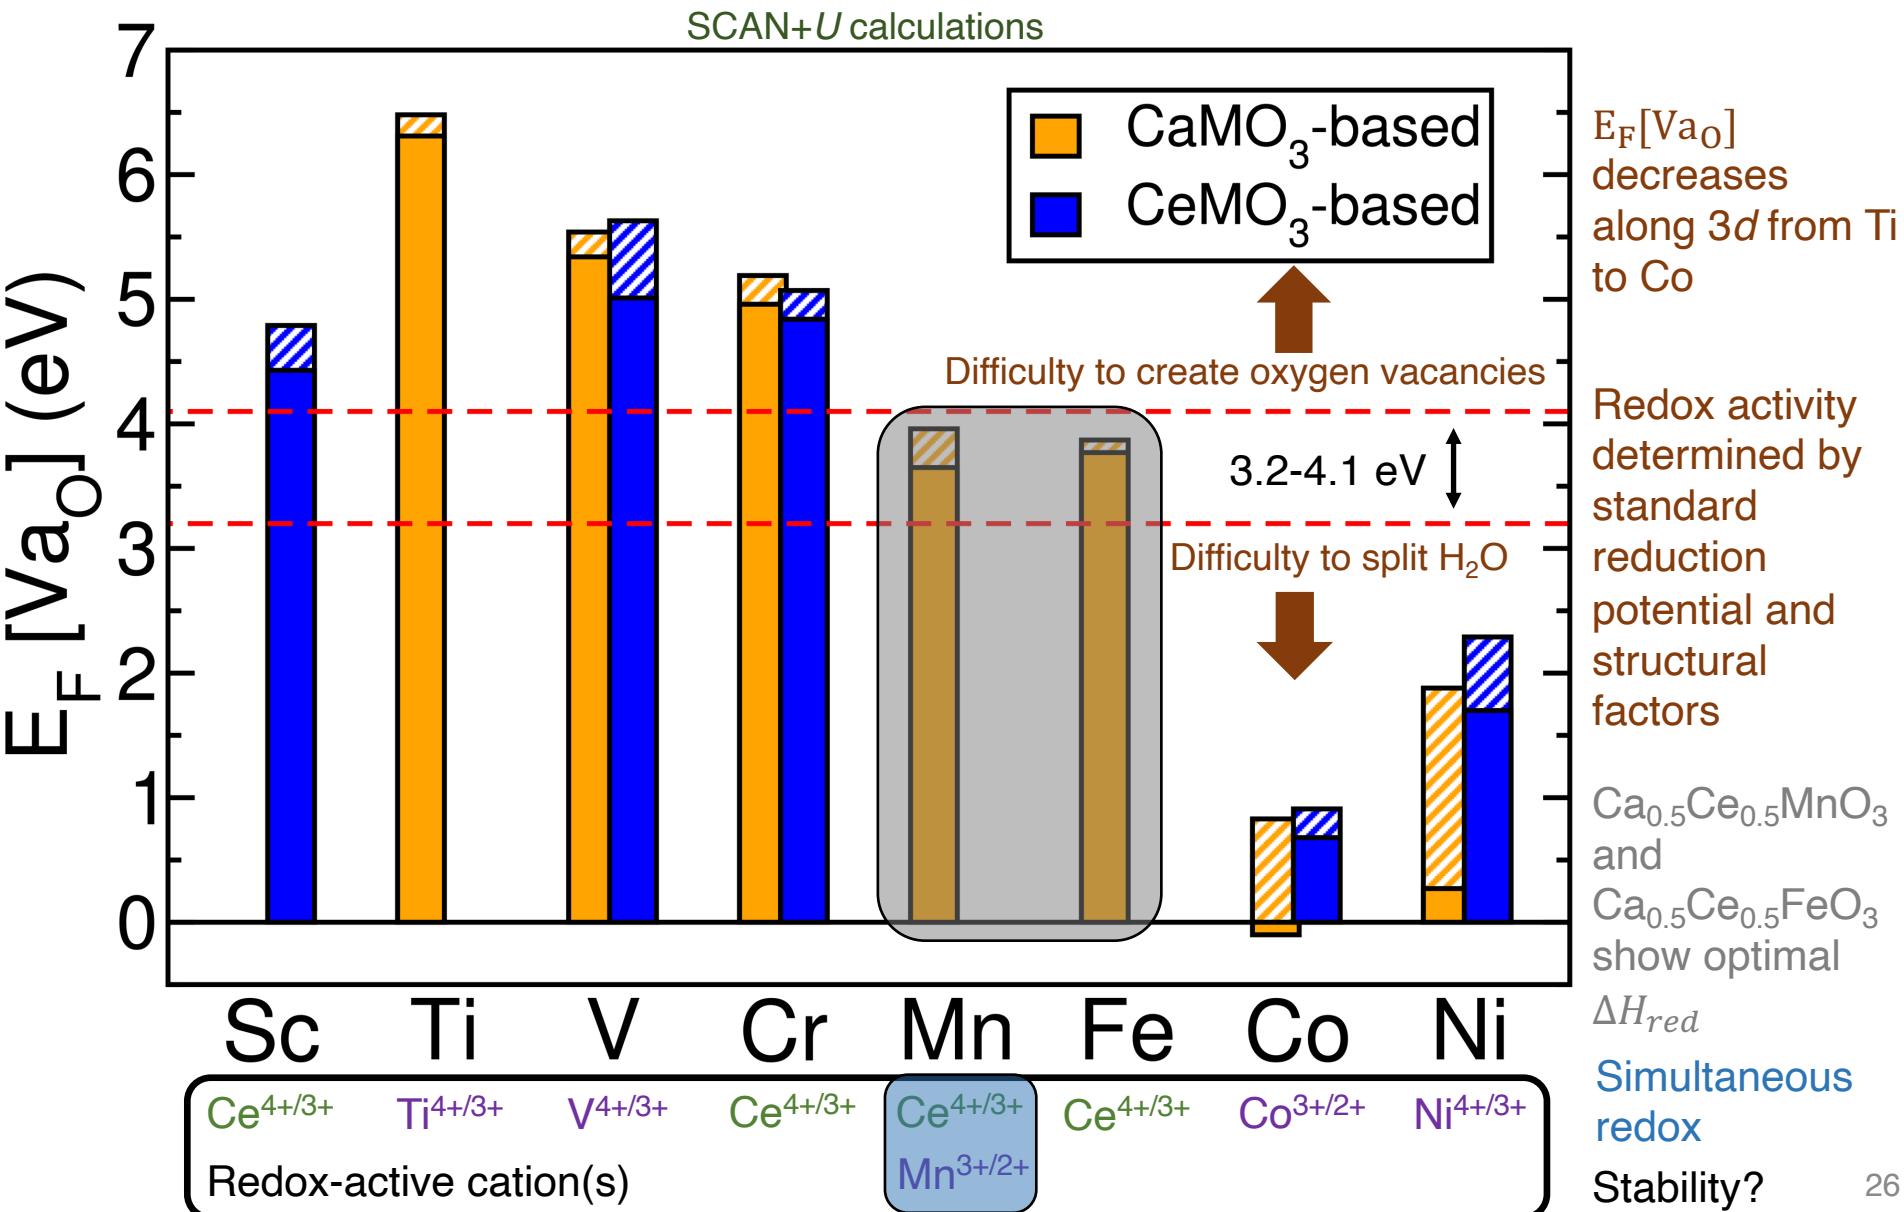

CeCoO₃ is highly unstable!

0 K stability: CaMO₃ and CeMO₃

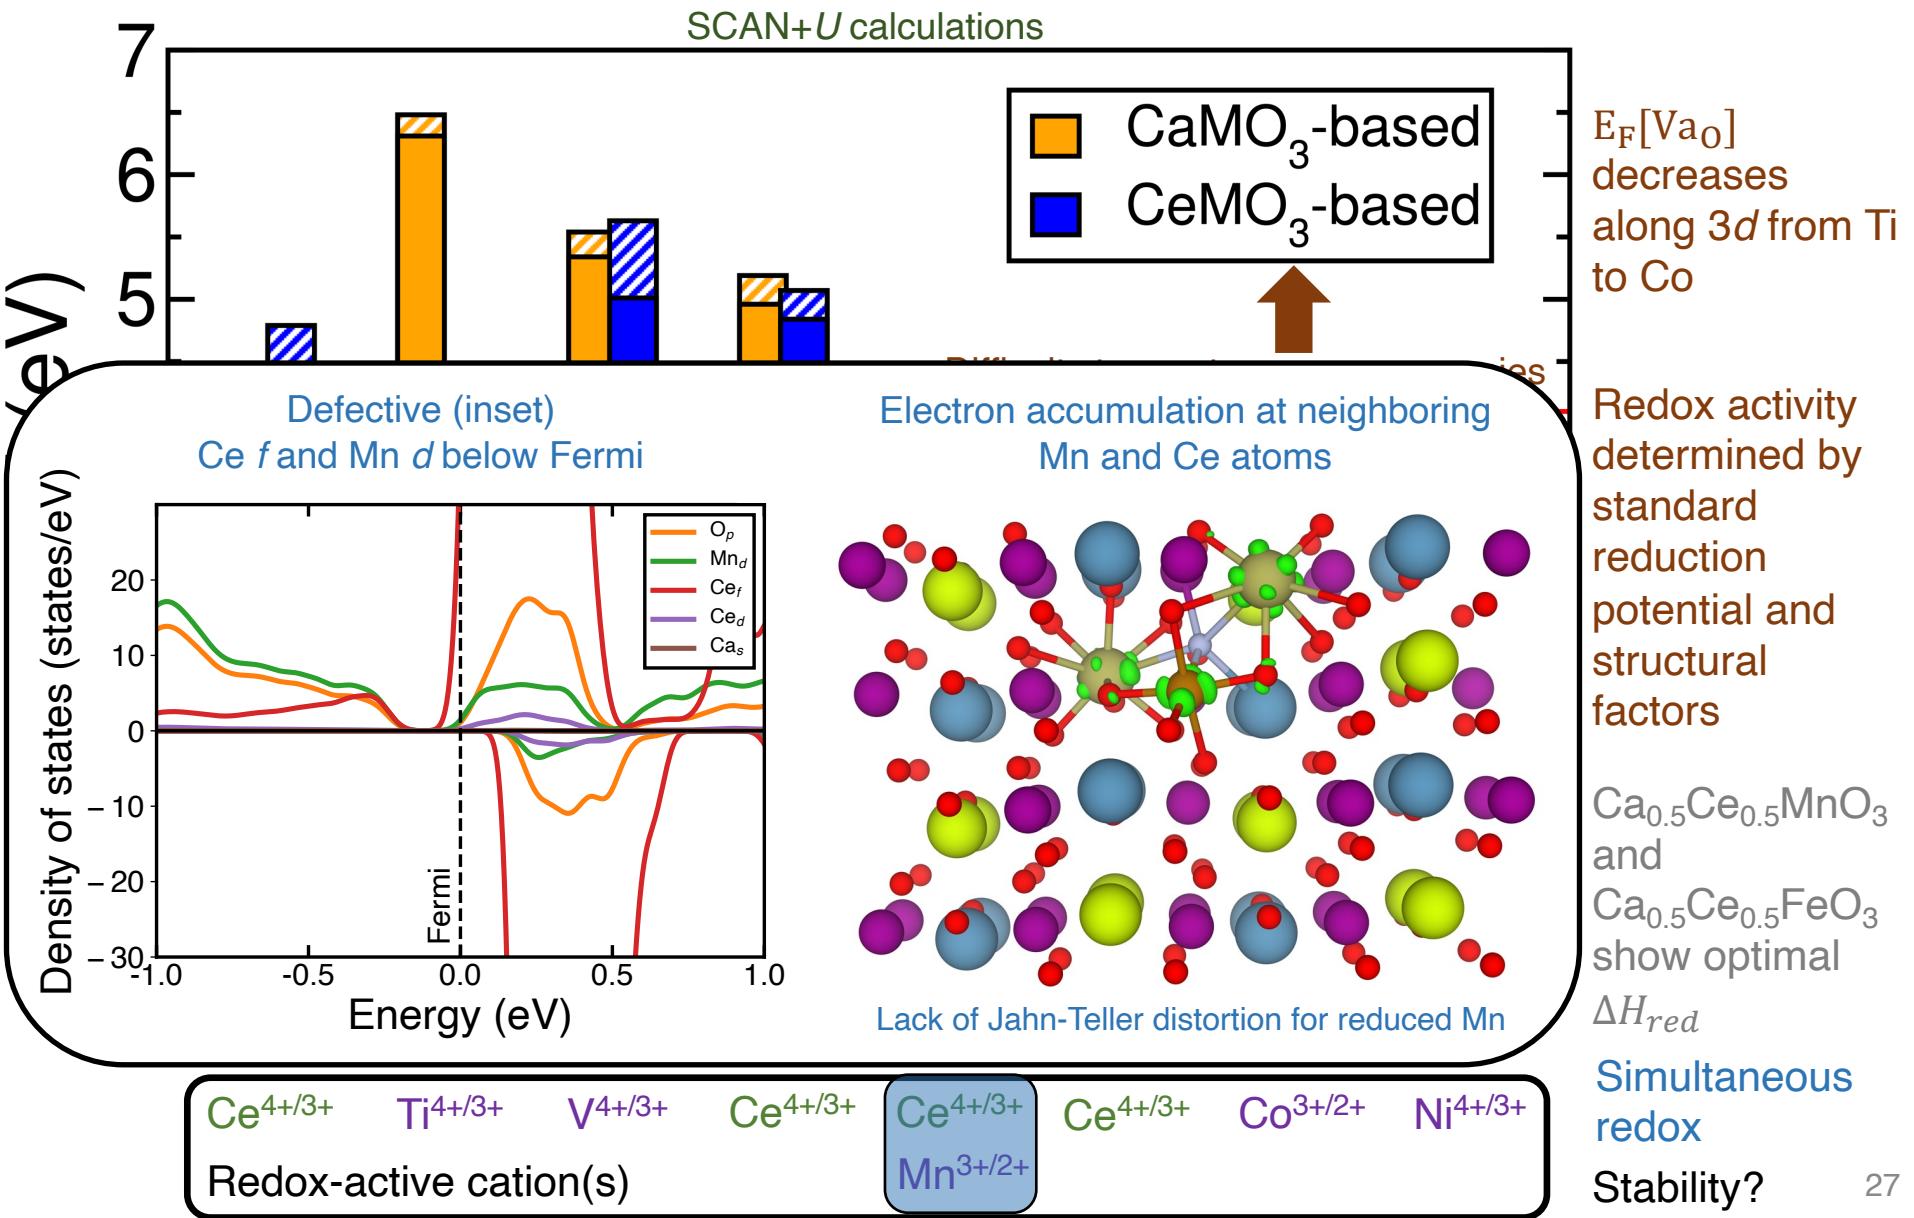

No candidates among ternaries in terms of simultaneous redox and optimal enthalpy of reduction: what about quaternaries?

Oxygen vacancy formation energy in $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{MO}_3$: $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{MnO}_3$ and $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{FeO}_3$ are promising

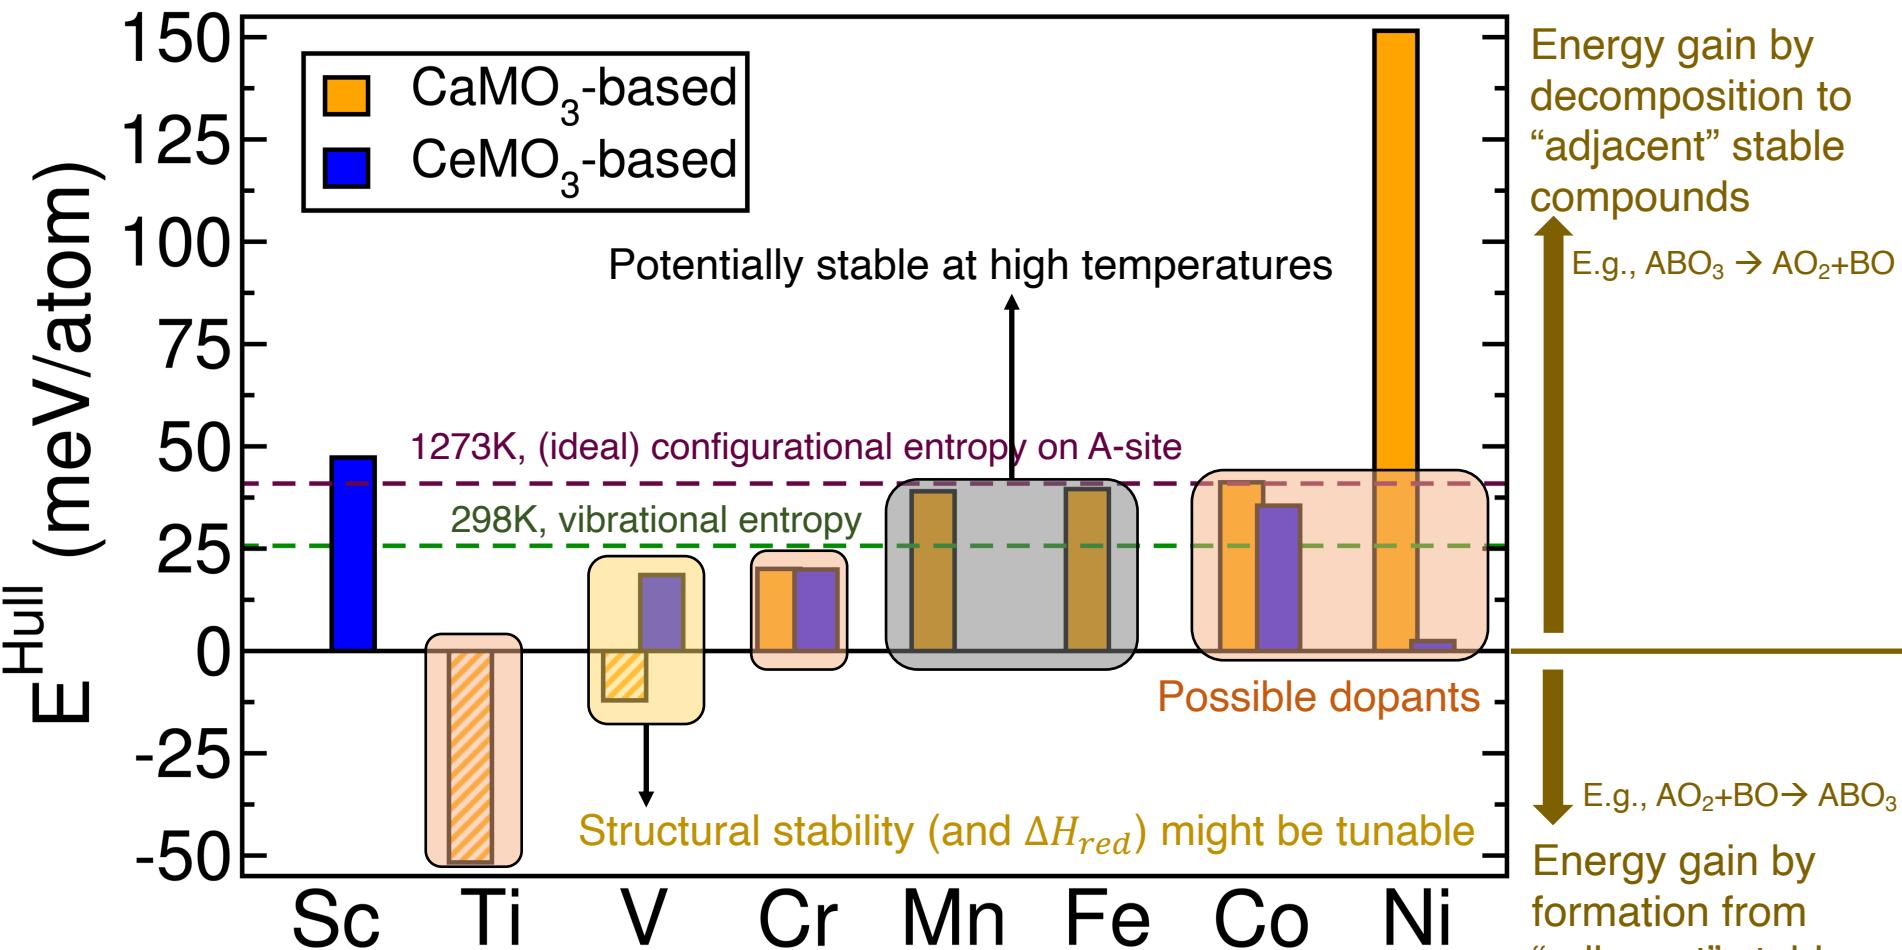

Oxygen vacancy formation energy in $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{MO}_3$: $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{MnO}_3$ and $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{FeO}_3$ are promising

0 K stability of $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{MO}_3$

Impact of configurational entropy (of not reduction)

$\text{Ca}_{1-x}\text{Ce}_x\text{MnO}_3$ ($x \sim 0.2$) has been synthesized before¹

$\text{Ca}_{0.5}\text{Ce}_{0.5}\text{MO}_3$ perovskites: can be stabilized at higher temperatures via A-site configurational entropy

Summary and outlook

- Need better materials for solar thermochemical water splitting
 - Durability, Capacity and Stability
- Search for perovskites with higher entropy of reduction for higher productivity
 - Simultaneous cation redox: $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{MnO}_3$ is a promising candidate
 - Candidates based on optimal enthalpy of reduction: $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{MnO}_3$, $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{FeO}_3$, $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{VO}_3$ (may be), and CeCoO_3 (unstable)
- Standard reduction potentials --a strong descriptor of vacancy formation energies
 - Particularly in ternaries, structural factors also dominate
 - Increasing Ca (Ce) concentration introduces weaker (stronger) Ca-O (Ce-O) bonds: decreases (increases) vacancy formation energy
- To do
 - Decouple factors contributing to vacancy formation, find other candidates
 - Quantify productivity and efficiency gains in $\text{Ca}_{0.5}\text{Ce}_{0.5}\text{MnO}_3$ (theory and experiments)
